[1] NEW (Net Explosive Weight) measured in lb. (pounds)

Notes: EIS = Environmental Impact Statement, FDM = Farallon de Medinilla, lb. = pounds, MITT = Mariana Islands Training and Testing, NEW = Net Explosive Weight (lb.), OEIS = Overseas EIS

Population-Level Impact Analysis

Under the Migratory Bird Treaty Act (MBTA) regulations applicable to military readiness activities (50 Code of Federal Regulation [CFR] part 21), the stressors introduced during training and testing activities would not result in a significant adverse effect on marine birds protected under the MBTA. While this determination is applicable to all marine birds that occur in the Study Area, the Navy carried out a focused analysis for marine birds known to breed within the Study Area, particularly for breeding marine birds on FDM. The Navy identified two birds in particular that have a heightened concern with regards to 50 CFR Part 21—the great frigatebird and the masked booby.

In the 2015 MITT Final EIS/OEIS, the Navy assessed the significance of injury and mortality of individual masked boobies and great frigatebirds relative to the viability of these species' populations. The populations of the masked booby and great frigatebird were defined based on (1) the distribution of subspecies *S. d. personata* and *F. m. palmerstoni*, (2) the colony locations within these distributions, and (3) the number of individual birds associated with these colonies. The Navy then compared the number of masked boobies and great frigatebirds that are found within the colonies within the Marianas (particularly FDM) to that of the regional population within the western and central Pacific.

Because the numbers of activities described in this SEIS/OEIS potentially affecting these birds and the amount of NEW used on FDM do not appreciably differ from what was analyzed previously, the conclusions within the 2015 MITT Final EIS/OEIS remain valid. These conclusions are summarized below:

- The great frigatebird may occasionally nest on FDM, which is one of only two small breeding colonies known to exist within the Mariana Islands (the other is located on Maug in the northern portion of the archipelago). FDM does not appear to be a temporally or spatially stable rookery location. Compared to the numbers of great frigatebirds estimated throughout central and western Pacific (10,000 pairs in the Hawaiian Islands, with other colonies on Howland, Baker, Jarvis, Johnston Atoll, and Christmas Island), and the apparent low numbers of great frigatebirds from historic times through the present within the Mariana archipelago, the direct and indirect effects on effects of military activities on FDM would not represent a significant adverse impact on the population of the great frigatebird.
- For the masked booby, FDM is the largest breeding colony in Mariana Islands. The colony numbers recorded by the Navy appear to be stable, and the data do not suggest any significant declines of masked booby numbers. Although the masked booby may be subject to short- and long-term impacts of military use of FDM and individuals likely suffer injury and mortality from some activities, FDM continues to support a relatively stable rookery. In the central and western Pacific, 2,500 pairs are estimated within the Northwestern Hawaiian Islands, Jarvis (up to 1,200 pairs), Barker Island (over 1,500 pairs), and smaller colonies in American Samoa, Palmyra, Johnson Atoll, and northern islands in the Mariana archipelago (Maug, Uracas, Guguan, and FDM). Based on the long-term use and stability of the masked booby breeding population on FDM and the wide geographic range and abundance of the masked booby throughout the Pacific, the effects of military use of FDM would not represent a significant adverse impact on the population of the masked booby.
- Pursuant with the Department of Defense's obligations under 50 CFR Part 21, the Department of Defense will continue to implement training restrictions on FDM (see Section 5.5, Terrestrial Mitigation Measures to be Implemented) and monitoring of bird populations on FDM.

3.6.2.1 Acoustic Stressors

Section 3.6.3.1 (Acoustic Stressors) in the 2015 MITT Final EIS/OEIS provided an overview of marine bird hearing, including an explanation of how birds can suffer injury, hearing loss, and physiological stress, as well as various behavioral reactions exhibited by birds when a noise event induces a response. In addition, long-term consequences associated with noise-induced impacts are discussed in the 2015 MITT Final EIS/OEIS in Section 3.6.3.1 (Acoustic Stressors).

3.6.2.1.1 Impacts from Sonar and Other Transducer Stressors Under Alternative 1

Under Alternative 1, the number of sonar hours used in the Study Area during training and testing activities compared to the number analyzed in the 2015 MITT Final EIS/OEIS (see Table 3.0-2 and Table 3.0-3 in this SEIS/OEIS) would decrease overall. Therefore, the analysis in the 2015 MITT Final EIS/OEIS remains valid. Decreases in sonar hours shown for activities proposed under Alternative 1 would have no appreciable change on the impact analysis or conclusions for acoustic stressors presented in the 2015 MITT Final EIS/OEIS, based on the analysis below.

Sonar and other transducers emit sound waves into the water to detect objects, safely navigate, and communicate. Use of sonar and other transducers would typically be transient and temporary. General categories of sonar systems are described in Section 3.0.4.1 (Acoustic Stressors).

Information regarding the impacts of sonar on birds is unavailable, and little is known about the ability for birds to hear underwater. The limited information and data from other species suggest the range of best hearing may shift to lower frequencies in water (Dooling & Therrien, 2012; Johansen et al., 2016; Therrien, 2014). Because few birds can hear above 10 kHz in air, it is likely that the only sonar sources they may be able to detect are low- and mid-frequency sources. Other than pursuit diving species, the exposure to birds by these sounds is likely to be negligible because they spend only a very short time underwater (plunge-diving or surface-dipping) or forage only at the water surface. Pursuit divers may remain underwater for minutes, increasing the chance of underwater sound exposure.

In addition to diving behavior, the likelihood of a bird being exposed to underwater sound depends on factors such as duty cycle (defined as the percentage of the time during which a sound is generated over a total operational period), whether the source is moving or stationary, and other activities that might be occurring in the area. When used, continuously active sonars transmit more frequently (greater than 80 percent duty cycle) than traditional sonars, but at a substantially lower source level. However, it should be noted that active sonar is rarely used continuously throughout the listed activities, and many sources are mobile. For moving sources such as hull-mounted sonar, the likelihood of an individual bird being repeatedly exposed to a sound source over a short period of time is low because the training and testing activities are transient, and sonar use and bird diving are intermittent. The potential for birds to be exposed to intense sound associated with stationary sonar sources would likely be limited for some training and testing activities because other activities occurring in conjunction may cause them to leave the immediate area. For example, birds would likely react to helicopter noise during dipping sonar exercises by flushing from the immediate area.

Injury due to acoustic resonance of air space in the lungs due to sonar and other transducers is unlikely in birds. Unlike mammals, birds have compact, rigid lungs with strong pulmonary capillaries that do not change much in diameter when exposed to extreme pressure changes (Baerwald et al., 2008), leading to resonant frequencies lower than the frequencies used for Navy sources.

A physiological impact, such as hearing loss, would likely only occur if a marine bird were close to an intense sound source. Hearing loss is typically quantified in terms of threshold shift—the amount (in dB) that hearing thresholds at one or more specified frequencies are elevated, compared to their pre-exposure values, at some specific time after the noise exposure. The amount of threshold shift measured usually decreases with increasing recovery time—the amount of time that has elapsed since a noise exposure. If the threshold shift eventually returns to zero (i.e., the hearing threshold returns to the pre-exposure value), the threshold shift is called a temporary threshold shift (TTS). If the threshold shift does not completely recover (the threshold remains elevated compared to the pre-exposure value), the remaining threshold shift is called a permanent threshold shift (PTS). By definition, TTS is a function of the recovery time, therefore comparing the severity of noise exposures based on the amount of induced TTS can only be done if the recovery times are also taken into account. For example, a 20 dB TTS measured 24 hours post-exposure indicates a more hazardous exposure than one producing 20 dB of TTS measured only two minutes after exposure; if the TTS is 20 dB after 24 hours, the TTS measured after two minutes would have likely been much higher. Conversely, if 20 dB of TTS was measured after two minutes, the TTS measured after 24 hours would likely have been much smaller.

In general, birds are less susceptible to both TTS and PTS than mammals (Saunders & Dooling, 1974). Diving birds have adaptations to protect the middle ear and tympanum from pressure changes during diving that may affect hearing (Dooling & Therrien, 2012). While some adaptions may exist to aid in underwater hearing, other adaptations to protect in-air hearing may limit aspects of underwater hearing (Hetherington, 2008). Because of these reasons, the likelihood of a diving bird experiencing an underwater exposure to sonar or other transducer that could result in an impact on hearing is considered low.

Because there is no new information since the 2015 MITT Final EIS/OEIS that would change the previous analysis for potential impacts on ESA-listed marine bird species, the conclusions in the 2015 MITT Final EIS/OEIS remain valid. The described training and testing activities would present no measurable chance for interaction with ESA-listed marine bird species (e.g., short-tailed albatross, Hawaiian petrel, Newell's shearwater). In the 2015 MITT Final EIS/OEIS and during consultation between the Navy and USFWS, the Navy determined that the use of sonar and other transducers would have no effect on ESA-listed marine birds.

Because of the small numbers of birds potentially exposed to stressors associated with sonar and other transducers, and the low potential of any injurious exposure to sonar and other transducers while birds are under water, marine bird population impacts would not occur.

Pursuant to the ESA, acoustic stressors from the use of sonar and other transducers during training and testing activities, as described under Alternative 1, would have no effect on ESA-listed Hawaiian petrels, short-tailed albatrosses, and Newell's shearwaters. This determination is consistent with the previous consultation between the Navy and USFWS for activities described in the 2015 MITT Final EIS/OEIS.

Under the MBTA regulations applicable to military readiness activities (50 CFR Part 21), the impacts from sonar and other transducers during training and testing activities described under Alternative 1 would not result in a significant adverse effect on populations of the great frigatebird, masked booby, or other marine bird populations.

3.6.2.1.2 Impacts from Sonar and Other Transducer Stressors under Alternative 2 (Preferred Alternative)

As with Alternative 1, the number of sonar hours used under Alternative 2 in the Study Area during training and testing activities compared to the number analyzed in the 2015 MITT Final EIS/OEIS (Table 3.0-2 and Table 3.0-3) would decrease overall. Therefore, the analysis in the 2015 MITT Final EIS/OEIS remains valid. Decreases in the number of training and testing activities would potentially decrease the level of acoustic stressors in the Study Area. The conclusions for ESA-listed species presented in the 2015 MITT Final EIS/OEIS is the same as for Alternative 1 in this SEIS/OEIS.

As with Alternative 1, taken together, the small numbers of birds potentially exposed to stressors associated with sonar and other transducers under Alternative 2, and the low potential of any injurious exposure to sonar and other transducers while birds are under water, there would be no impacts on marine bird populations.

Pursuant to the ESA, acoustic stressors from the use of sonar and other transducers during training and testing activities, as described under Alternative 2, would have no effect on ESA-listed Hawaiian petrels, short-tailed albatrosses, and Newell's shearwaters. This determination is consistent with the previous consultation between the Navy and USFWS for activities described in the 2015 MITT Final EIS/OEIS.

Under the MBTA regulations applicable to military readiness activities (50 CFR Part 21), the impacts from sonar and other transducers during training and testing activities described under Alternative 2 would not result in a significant adverse effect on populations of the great frigatebird, masked booby, or other marine bird populations.

3.6.2.1.2.1 Impacts from Sonar and Other Transducer Stressors under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Acoustic stressors as listed above would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer acoustic stressors within the marine environment where Navy activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for impacts on marine birds from sonar and other transducers, but would not measurably improve the overall distribution or abundance of marine birds.

3.6.2.1.3 Impacts from Aircraft Noise

Section 3.6.3.1.3.1 (Fixed-Wing Aircraft) and Section 3.6.1.3.2 (Helicopters) of the 2015 MITT Final EIS/OEIS discuss the different types of aircraft and the noise they generate, along with a summary of potential responses marine birds may exhibit. Since the publication of the 2015 MITT Final EIS/OEIS, no new information was identified during the Navy's literature review that would substantially alter the assessment of potential impacts on marine birds from aircraft noise. Therefore, the information contained in Section 3.6.3.1.3.3 (Vessels) of the 2015 MITT Final EIS/OEIS remains valid.

Birds in areas that may experience repeated exposure often habituate and do not respond behaviorally (Larkin et al., 1996; National Park Service, 1994; Plumpton, 2006). Throughout the Study Area, repeated exposure of individual birds or groups of birds is unlikely based on the dispersed nature of the overflights and the capability of birds to avoid or rapidly vacate an area of disturbance. Therefore, the

general health of individual birds would not be compromised. Occasional startle or alert reactions to aircraft noise are not likely to disrupt major behavior patterns (such as migrating, breeding, feeding, and sheltering) or to result in serious injury to any birds.

Training and testing activities where aircraft are used typically occur further offshore; however, increased use of FDM may increase the potential for aircraft strike of birds. Therefore, for the purposes of this SEIS/OEIS, only the use of aircraft related to FDM training activities are discussed below under the alternatives analysis for birds for this stressor category.

3.6.2.1.3.1 Impacts from Aircraft Noise Stressors Under Alternative 1

Under Alternative 1, the number of proposed activities including aircraft would decrease overall throughout the study area (see Table 3.0-11). In the open ocean, marine birds would be exposed to additional aircraft noise sources, but these activities are spread out throughout the Study Area. Because of the increase in munitions use at FDM, however, aircraft overflights over FDM would increase, depending on the delivery platform. For example, some of the increases are associated with ship to surface, while others may involve helicopters and fixed-wing aircraft. Therefore, the analysis in this section focuses on FDM, where actual aircraft overflights would likely increase.

Increased training activities under Alternative 1 would increase the potential for noise exposures for birds on FDM because the increase in the number of training activities would require more aircraft to fly over the island (potentially at low altitude) and land on the island to deliver and pick up personnel. As shown in Table 2.5-1, activities that would increase aircraft overflights include Missile Exercise and Direct Action (Tactical Air Control Party) activities.

Aircraft overflights are expected to elicit short-term behavioral responses in nesting birds at FDM. Based on studies from other nesting bird areas (Barnas et al., 2018; Bowles, 1995; Larkin et al., 1996), any period away from the nest would last a few seconds to a few minutes, which is likely not long enough for opportunistic predation of a nest (e.g., by rats on FDM). The 2015 MITT Final EIS/OEIS analyzed other adverse effects, such as damage to eggs and startling of juveniles and adults.

Anecdotally, some birds typically take flight while roosting or nesting during quarterly helicopter-based marine bird surveys over FDM; birds that are stationary and not on the wing are counted (U.S. Department of the Navy, 2013a). Although no studies are available specific to marine bird responses to low-level overflights over FDM, other studies of shorebird responses to military aircraft overflights are helpful. Black (2005), studied the effects of low-altitude (less than 500 ft. [152 m] above ground level) military training flights with sound levels from 55 to 100 A-weighted decibels on wading bird colonies (i.e., great egret, snowy egret, tricolored heron, and little blue heron). The training flights involved three or four aircraft and occurred once or twice per day. This study concluded that the reproductive activity—including nest success, nestling survival, and nestling chronology—was independent of F-16 overflights. Dependent variables were more strongly related to ecological factors, including location and physical characteristics of the colony and climatology. Another study on the effects of circling fixed-wing aircraft and helicopter overflights on wading bird colonies found that at altitudes of 195 ft. (59 m) to 390 ft. (119 m), there was no reaction in nearly 75 percent of the 220 observations. Ninety percent displayed no reaction or merely looked toward the direction of the noise source. Another 6 percent stood up, 3 percent walked from the nest, and 2 percent flushed (but were without active nests) and returned within five minutes (Kushlan, 1978).

These studies, coupled with anecdotal observations on FDM during quarterly marine bird monitoring surveys, suggest that aircraft overflights do not have harmful effects on nesting and roosting marine birds on FDM, and that the behavioral responses are short term (Camp et al., 2016).

Although some degree of disturbance is expected from the increase in aircraft noise over FDM, the island will likely continue to serve as an important rookery for regional species without long-term significant impacts on marine bird populations. As discussed in Section 3.6.1.7 (Rookery Locations and Breeding Activities on FDM), Camp et al. (2016) published results of multi-year population monitoring of three species of boobies on FDM, showing that there is some evidence that masked and red-footed booby populations on FDM have declined, while brown booby populations have increased. However, the general conclusion is that all three species exhibited population fluctuations over time. Combined with the level of variability observed in the count data, this precluded any definite conclusions about long-term population trends (i.e., the data were non-significant) (Camp et al., 2016).

Because of the dispersed nature of overflights in open ocean training areas, birds or groups of birds in pelagic environments would not likely be exposed to repeated overflights. Because any exposures would be infrequent, and these exposures would not cause injury, population impacts would not occur for bird species in the open ocean.

Aircraft activity described in this SEIS/OEIS would present no measurable chance for interaction with ESA-listed marine bird species (e.g., short-tailed albatross, Hawaiian petrel, Newell's shearwater). In the 2015 MITT Final EIS/OEIS and during consultation between the Navy and USFWS, the Navy determined that aircraft activity would have no effect on ESA-listed marine birds. Although the amount of training and testing activities using aircraft would increase compared to the 2015 MITT Final EIS/OEIS, the potential for geographic and temporal overlap would remain negligible; therefore, the conclusions for ESA-listed species presented in the 2015 MITT Final EIS/OEIS is the same as for Alternative 1 in this SEIS/OEIS.

Pursuant to the ESA, aircraft noise during training activities, as described under Alternative 1, would have no effect on ESA-listed Hawaiian petrels, short-tailed albatrosses, and Newell's shearwaters. This determination is consistent with the previous consultation between the Navy and USFWS for activities described in the 2015 MITT Final EIS/OEIS.

Under the MBTA regulations applicable to military readiness activities (50 CFR Part 21), the impacts from aircraft noise during training activities described under Alternative 1 would not result in a significant adverse effect on populations of the great frigatebird, masked booby, or other marine bird populations.

3.6.2.1.3.2 Impacts from Aircraft Noise Stressors Under Alternative 2 (Preferred Alternative)

Under Alternative 2, the number of activities including aircraft would decrease compared to levels analyzed under the 2015 MITT Final EIS/OEIS, but would be more than proposed under Alternative 1 (see Table 3.0-11).

As with Alternative 1, the dispersed nature of overflights in open ocean training areas under Alternative 2 would not likely expose birds or groups of birds in pelagic environments to repeated overflights. Because any exposures would be infrequent, and these exposures would not cause injury, population impacts would not occur for bird species in the open ocean.

No additional targets would be used, and this activity would be constrained by confining targeting to specific sites within designated impact zones. Because the same locations would be used for targeting activities, the impacts of Alternative 2 are the same as Alternative 1. In the open ocean, marine birds

would be exposed to additional aircraft noise sources, but these activities are spread out throughout the Study Area, and the potential impacts of at-sea training and testing activities would not be discernable from Alternative 1. Therefore, impacts on marine birds under Alternative 2 from aircraft noise would be negligible.

Pursuant to the ESA, aircraft noise during training activities, as described under Alternative 2, would have no effect on ESA-listed Hawaiian petrels, short-tailed albatrosses, and Newell's shearwaters. This determination is consistent with the previous consultation between the Navy and USFWS for activities described in the 2015 MITT Final EIS/OEIS.

Under the MBTA regulations applicable to military readiness activities (50 CFR Part 21), the impacts from aircraft noise during training activities described under Alternative 2 would not result in a significant adverse effect on populations of the great frigatebird, masked booby, or other marine bird populations.

3.6.2.1.3.3 Impacts from Aircraft Noise Stressors Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Acoustic stressors as listed above would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer acoustic stressors within the marine environment where Navy activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for impacts on marine birds from aircraft noise, but would not measurably improve the overall distribution or abundance of marine birds.

3.6.2.1.4 Impacts from Weapons Noise

Sounds produced by weapons firing (muzzle blast), launch boosters, and projectile travel are potential stressors to birds and are discussed as impulsive noise under Section 3.6.3.1.2.2 (Explosions on Land and In-Air) in the 2015 MITT Final EIS/OEIS. Since the publication of the 2015 MITT Final EIS/OEIS, no new information was identified during the Navy's literature review that would substantially alter the assessment of potential impacts on marine birds from weapons noise.

3.6.2.1.4.1 Impacts from Weapons Noise Stressors Under Alternative 1

Under Alternative 1, the number of training and testing activities that would expose marine birds to weapons noise would decrease throughout the Study Area, compared to levels analyzed in the 2015 MITT Final EIS/OEIS (Table 3.0-14 and Table 3.0-16). A bird in the open ocean could be exposed to weapons noise if not already displaced by the visual or noise disturbance of a vessel supporting weapons-firing exercises. The firing of a weapon may have several components of associated noise. Firing of guns could include sound generated in air by firing a gun (muzzle blast) and a crack sound due to a low-amplitude shock wave generated by a supersonic projectile flying through the air. Most in-air sound would be reflected at the air-water interface. Underwater sounds would be strongest just below the surface and directly under the firing point. Any sound that enters the water only does so within a narrow cone below the firing point or path of the projectile. Vibration from the blast propagating through a ship's hull, the sound generated by the impact of an object with the water surface, and the sound generated by launching an object underwater are other sources of impulsive sound in the water.

Supersonic projectiles, which would be similar in size to shells fired from 5-inch/54 guns, would travel at approximately 2,600 ft./second, creating a bow shock wave. Pater and Shea (1981) measured the characteristics of a bow shock wave from a 5-inch projectile and found that the shock wave ranged from 40 to 147 dB re 20 µPa sound pressure level peak taken at the ground surface at 1,100 m from the firing location and 190 m perpendicular from the trajectory (for safety reasons). Shells fired from a kinetic energy weapon are considered hypersonic, and would travel at about 6,500 ft./second, and peak pressures would be expected to be several dB higher than for shell velocities described by (Pater & Shea, 1981). By definition, bow shock waves, regardless of shell velocity, would travel at the speed of sound in air. Marine birds would be exposed to this type of noise for a very brief period of time (a few seconds), and would likely cause brief and temporary behavioral reactions described previously for other in-air noise disturbances.

Sound due to missile and target launches is typically at a maximum at initiation of the booster rocket and rapidly fades as the missile or target travels downrange. Birds foraging or migrating through a training area in the open ocean may respond by avoiding areas where weapons-firing exercises occur. Exposures of most marine birds would be infrequent, based on the brief duration and dispersed nature of the vessels, and the brief duration of the weapons-firing noise. If a bird responds to weapons noise, only short-term behavioral responses such as startle responses, head turning, or avoidance responses would be expected. Weapons noise near rookery locations (only at FDM) may induce startle responses, inducing birds to temporarily leave nests. Because impacts on individual birds, if any, are expected to be minor and limited, no long-term consequences to individuals are expected. Accordingly, there would be no consequences to any bird populations, and weapons noise would not have a significant adverse effect on populations of migratory bird species.

On FDM, however, marine birds would likely be exposed to increased weapons noise because of the increase in the number of explosive and non-explosive munitions (see Table 3.6-1, Table 3.6-2, and Table 3.6-3). Sources of weapons generating noise at the time of weapons firing on or near FDM include small-caliber rounds, rockets, medium-caliber projectiles, and large-caliber projectiles. Other munitions types used on FDM (e.g., non-explosive practice munition and explosive bombs and missiles) are launched far from the target (impact areas on FDM) or released from aircraft.

The potential impacts of explosives noise and weapons firing noise on FDM's wildlife are discussed in Section 3.10.3.1.1 (Impacts from Explosives and Weapons Firing Noise) in Section 3.10 (Terrestrial Species and Habitats) of this SEIS/OEIS, which provides a summary of the different types of sounds, frequency ranges, and intensity of sounds generated from munitions use on FDM. Sources of noise from weapons firing that may be heard by marine birds on FDM include close-in weapons firing from vessels, helicopters, close-combat surface firing from fixed-wing aircraft, and surface firing, with the largest increase in munitions use resulting from small arms, medium-caliber explosives, and mortar and grenade use during Direct Action training activities. As shown in Table 3.6-1, the number of training events for this activity type would stay the same compared to what was previously analyzed in the 2015 MITT Final EIS/OEIS; however, the number of munitions used would increase during each training event (see Table 3.6-2). These training events would occur within the Northern Special Use Area and fire into the impact areas towards the south; therefore, more birds would be exposed to more weapons firing noise under Alternative 1 because of the increased number of small-caliber rounds, medium-caliber explosives, and grenades and mortars fired into impact areas from the Northern Special Use Area. The weapons-firing noise would likely be masked somewhat by natural sounds on FDM, such as waves and winds. The impulsive sound caused by weapon firings would have limited potential to mask any

important biological sound simply because the duration of the impulse is brief, even when multiple shots are fired in series.

Although some degree of disturbance is expected from the increase in weapons noise on FDM, the island will likely continue to serve as an important rookery for regional species without long-term significant impacts on marine bird populations. As discussed in Section 3.6.1.7 (Rookery Locations and Breeding Activities on FDM), Camp et al. (2016) published results of multi-year population monitoring of three species of boobies on FDM, showing that there is some evidence that masked and red-footed booby populations on FDM have declined, while brown booby populations have increased. However, the general conclusion is that all three species exhibited population fluctuations over time. Combined with the level of variability observed in the count data, this precluded any definite conclusions about long-term population trends (i.e., the data were non-significant) (Camp et al., 2016).

Weapons noise would present no measurable chance for interaction with ESA-listed marine bird species (short-tailed albatross, Hawaiian petrel, Newell's shearwater). As discussed previously, ESA-listed marine bird species do not occur on FDM (or any other island within the Marianas) and have little to no overlap with the Study Area. In the 2015 MITT Final EIS/OEIS and during consultation between the Navy and USFWS, the Navy determined that weapons noise would have no effect on ESA-listed marine birds. Although the amount of training and testing activities would increase compared to the 2015 MITT Final EIS/OEIS, the potential for geographic and temporal overlap would remain negligible; therefore, the conclusions for ESA-listed species presented in the 2015 MITT Final EIS/OEIS is the same as for Alternative 1 in this SEIS/OEIS.

Pursuant to the ESA, weapons noise during training and testing activities, as described under Alternative 1, would have no effect on ESA-listed Hawaiian petrels, short-tailed albatrosses, and Newell's shearwaters. This determination is consistent with the previous consultation between the Navy and USFWS for activities described in the 2015 MITT Final EIS/OEIS.

Under the MBTA regulations applicable to military readiness activities (50 CFR Part 21), the impacts from weapons noise during training and testing activities described under Alternative 2 would not result in a significant adverse effect on populations of the great frigatebird, masked booby, or other marine bird populations.

3.6.2.1.4.2 Impacts from Weapons Noise Stressors Under Alternative 2 (Preferred Alternative)

As with Alternative 1, under Alternative 2 the number of training and testing activities that would expose marine birds to weapons noise would decrease throughout the Study Area, compared to levels analyzed in the 2015 MITT Final EIS/OEIS (see Table 3.0-14 and Table 3.0-16). Compared to Alternative 1, there would be small increases in the number of activities using large-caliber and medium-caliber projectiles and missiles under Alternative 2 for at-sea training and testing activities. Therefore, Alternative 2 would introduce fewer weapons firing events than activities analyzed in the 2015 MITT Final EIS/OEIS for at-sea activities. Because activities would occur within the same locations as with Alternative 1, at-sea weapons firing activities would be widely dispersed, and marine birds would also be widely dispersed, the impacts of Alternative 2 are the same as for Alternative 1.

On FDM, the only training activity that would introduce weapons firing noise is Direct Action (tactical control party). As shown in Table 3.6-1, the number of training events for this activity type would stay the same compared to what was previously analyzed in the 2015 MITT Final EIS/OEIS and compared to Alternative 1; however, the number of munitions used would increase (see Table 3.6-2). These training

events would occur within the Northern Special Use Area and fire into the impact areas towards the south; therefore, more birds would be exposed to more weapons firing noise under Alternative 2 because of the increased number of small-caliber rounds, medium-caliber explosives, and grenades and mortars fired into impact areas from the Northern Special Use Area. The weapons-firing noise would likely be masked somewhat by natural sounds on FDM, such as waves and winds. The impulsive sound caused by weapon firings would have limited potential to mask any important biological sound simply because the duration of the impulse is brief, even when multiple shots are fired in series.

As with Alternative 1, some degree of disturbance is expected from the increase in weapons noise on FDM; however, the island will likely continue to serve as an important rookery for regional species without long-term significant impacts on marine bird populations. As discussed in Section 3.6.1.7 (Rookery Locations and Breeding Activities on FDM), Camp et al. (2016) published results of multi-year population monitoring of three species of boobies on FDM, showing that is some evidence that masked and red-footed booby populations on FDM have declined, while brown booby populations have increased. However, the general conclusion is that all three species exhibited population fluctuations over time. Combined with the level of variability observed in the count data, this precluded any definite conclusions about long-term population trends (i.e., the data were non-significant) (Camp et al., 2016). The same conclusions for Alternative 1 for MBTA-protected marine bird species at sea and on FDM, and ESA-listed marine bird species at sea, are applicable to Alternative 2.

Pursuant to the ESA, weapons noise during training and testing activities, as described under Alternative 1, would have no effect on ESA-listed Hawaiian petrels, short-tailed albatrosses, and Newell's shearwaters. This determination is consistent with the previous consultation between the Navy and USFWS for activities described in the 2015 MITT Final EIS/OEIS.

Under the MBTA regulations applicable to military readiness activities (50 CFR Part 21), the impacts from weapons noise during training and testing activities described under Alternative 2 would not result in a significant adverse effect on populations of the great frigatebird, masked booby, or other marine bird populations.

3.6.2.1.4.3 Impacts from Weapons Noise Stressors Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Acoustic stressors would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer acoustic stressors within the marine environment where Navy activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for impacts on marine birds from weapons noise, but would not measurably improve the overall distribution or abundance of marine birds.

3.6.2.2 Explosives Stressors (explosive shock wave and sound, explosive fragments)

Section 3.6.3.1.2 (Impacts from Explosives and Swimmer Defense Airguns) in the 2015 MITT Final EIS/OEIS discusses the sources and potential impacts of explosives noise on marine birds (e.g., injury, hearing loss, physiological stress, masking, and long-term consequences of exposures). Explosions in the water, near the water surface, on land (FDM), and in the air can introduce loud, impulsive, broadband

sounds into the marine environment. However, unlike other acoustic stressors, explosives release energy at a high rate, producing a shock wave that can be injurious and even deadly. The information regarding training and testing activities in open ocean training environments that generate explosives noise has not changed since the publication of the 2015 MITT Final EIS/OEIS. Therefore, this section focuses on the potential for increased training activities to impact birds on FDM proposed under the alternatives described in this SEIS/OEIS.

Noise can result from direct munitions impacts (one object striking another), blasts (explosions that result in shock waves), bow shock waves (pressure waves from projectiles flying through the air), and substrate vibrations (combinations of explosion, recoil, or vehicle motion with the ground). Noise may be continuous (i.e., lasting for a long time without interruption) or impulse (i.e., short duration). Continuous impulses (e.g., helicopter rotor noise, bursts from rapid-fire weapons) represent an intermediate type of sound and, when repeated rapidly, may resemble continuous noise. These types of sound are distinguished here as they differ in their effects. Continuous sounds can result in hearing damage, while impulses typically elicit physiological or behavioral responses. Some birds may be killed or injured during these activities, or expend energy stores needed for migration to avoid perturbations generated by explosions.

Because the military will continue to implement mitigation measures designed to avoid or reduce impacts on terrestrial biological resources, all additional ordnance use would still be targeted at existing impact areas.

FDM has three impact areas, a special use area on the northern portion of the island, and a special use area on the land bridge. Since the release of the 2015 Final EIS/OEIS, the Navy has moved gunnery targets into the impact areas from their previous locations near the west-facing cliffs. Targets were relocated in order to minimize impacts on the cliff face. Targeting of areas inside of the special use areas and other areas outside of impact areas are prohibited. In other words, all areas outside of the impact areas are considered “no-fire areas.” Any ordnance that inadvertently lands outside of impact areas, including special use areas and in water, must be reported to Mariana Islands Range Complex Operations, in accordance with Commander, U.S. Naval Forces Marianas Instruction 3500.4A (U.S. Department of the Navy, 2011). The impact areas and special use areas are described below:

- **Northern Special Use Area**. Reserved for direct action (tactical air control party) type exercises and personnel recovery. This area is about 41 acres (ac.) (17 hectares [ha]) and includes a landing zone. Weapons may be fired from the special use area into impact areas, such as small-caliber rounds, grenades, and mortars.
- **Impact Area 1**. This area contains high-fidelity target structures and is comprised of vehicle shells and cargo containers. This area is authorized for inert ordnance only, and operators are required to report any live ordnance inadvertently dropped into Impact Area 1 to Mariana Islands Range Complex Operations. Impact Area 1 contains 10 targets of varying shapes and sizes, including four vehicles and six targets comprised of shipping containers.
- **Impact Area 2**. Impact Area 2 may be used for both live and inert ordnance. Strafing is permitted in this area. Impact Area 2 is about 22 ac. (9 ha).
- **Land Bridge**. The land bridge is designated as a “no target zone.” Operators are required to report ordnance observed impacting the land bridge.

- **Impact Area 3**. This area is south of the land bridge and authorized for inert ordnance, although live ordnance may be used only with prior approval from Joint Region Marianas. Strafing is permitted in this area. Impact Area 3 is about 11 ac. (4.5 ha).

3.6.2.2.1 Impacts from Explosive Stressors Under Alternative 1

Under Alternative 1, there would be an overall decrease throughout the Study Area in the number of explosive munitions used during training and testing activities compared to the number analyzed in the 2015 MITT Final EIS/OEIS (Table 3.0-16).

As shown in Table 3.6-1, there would be an increase in the number of events using FDM as a training location or target, with an increase in the number of munitions items expended on FDM (see Table 3.6-2).

Taken together, the increase in the number of training events per year or the amount of ordnance used during training events would result in an increase in the amount of NEW expended on FDM each year (see Table 3.6-1, Table 3.6-2, and Table 3.6-3). Although the amount of increased NEW is negligible, the potential exposure to stressors associated with ordnance use would increase under Alternative 1 compared to what was analyzed previously in the MITT Final EIS/OEIS. Factors that limit the potential for additional adverse impacts, however, include maintaining the same ordnance type and targeting restrictions included as part of the 2015 MITT Final EIS/OEIS. All ordnance expended on FDM would target existing impact zones, with the same ordnance restrictions imposed on all FDM activities and with the same avoidance and minimization measures in place (see Section 5.5, Terrestrial Mitigation Measures to be Implemented; and Table 5.5-1). Therefore, the increases in ordnance use on FDM do not appreciably change the impact conclusions presented in the 2015 MITT Final EIS/OEIS. The conclusions for ESA-listed marine bird species and other marine bird species protected by the MBTA included in the 2015 MITT Final EIS/OEIS remain valid.

Explosives would present no measurable chance for interaction with ESA-listed marine bird species (short-tailed albatross, Hawaiian petrel, Newell's shearwater). In the 2015 MITT Final EIS/OEIS and during consultation between the Navy and USFWS, the Navy determined that training and testing activities using explosives would have no effect on ESA-listed marine birds. Despite the continued at-sea use of explosives compared to the 2015 MITT Final EIS/OEIS, the potential for geographic and temporal overlap would remain negligible; therefore, the conclusions for ESA-listed species presented in the 2015 MITT Final EIS/OEIS is the same as for Alternative 1 in this SEIS/OEIS.

Pursuant to the ESA, explosives used during training and testing activities, as described under Alternative 1, would have no effect on ESA-listed Hawaiian petrels, short-tailed albatrosses, Newell's shearwaters. This determination is consistent with the previous consultation between the Navy and USFWS for activities described in the 2015 MITT Final EIS/OEIS.

Under the MBTA regulations applicable to military readiness activities (50 CFR Part 21), the impacts from explosives stressors during training and testing activities using explosives described under Alternative 1 would not result in a significant adverse effect on populations of the great frigatebird, masked booby, or other marine bird populations.

3.6.2.2.2 Impacts from Explosive Stressors Under Alternative 2 (Preferred Alternative)

As with Alternative 1, there would be an overall decrease throughout the Study Area in the number of explosive munitions used during at-sea training and testing activities compared to the number analyzed in the 2015 MITT Final EIS/OEIS. The number of explosive stressors under Alternative 2 would increase

as compared to Alternative 1 (see Table 3.0-16), but the conclusions for at-sea activities remains the same. Under Alternative 2, there would be an increase in the number of training events using FDM as a training location or target (see Table 3.6-1), with an increase in the number of munitions items expended on FDM (see Table 3.6-2) compared to what was analyzed previously in the MITT Final EIS/OEIS and under Alternative 1.

Taken together, the increase in the number of training events per year or the amount of ordnance used during events would result in an increase in the amount of NEW expended on FDM each year (see Table 3.6-3). Although the amount of increased NEW is negligible, the potential exposure to stressors associated with ordnance use would increase under Alternative 2 compared to what was analyzed previously in the MITT Final EIS/OEIS. Under Alternative 2, Naval Surface Firing Exercise events would expend more large-caliber projectiles, thereby increasing the NEW expended under Alternative 2 compared to Alternative 1. Factors that limit the potential for additional adverse impacts, however, include maintaining the same ordnance type and targeting restrictions included as part of the 2015 MITT Final EIS/OEIS. All ordnance expended on FDM would target existing impact zones, with the same ordnance restrictions imposed on all FDM activities and with the same avoidance and minimization measures in place (see Section 5.5, Terrestrial Mitigation Measures to be Implemented; and Table 5.5-1). Therefore, the increases in ordnance use on FDM shown in Tables 2.5-1 and 2.5-2 do not appreciably change the impact conclusions presented in the 2015 MITT Final EIS/OEIS. The conclusions for ESA-listed marine bird species and other marine bird species protected by the MBTA included in the 2015 MITT Final EIS/OEIS remain valid.

Explosives would present no measurable chance for interaction with ESA-listed marine bird species (short-tailed albatross, Hawaiian petrel, Newell's shearwater). In the 2015 MITT Final EIS/OEIS and during consultation between the Navy and USFWS, the Navy determined that training and testing activities using explosives would have no effect on ESA-listed marine birds. Although the amount of training and testing activities using explosives would increase compared to the 2015 MITT Final EIS/OEIS, the potential for geographic and temporal overlap would remain negligible; therefore, the conclusions for ESA-listed species presented in the 2015 MITT Final EIS/OEIS is the same as for Alternative 1 in this SEIS/OEIS.

Pursuant to the ESA, explosives used during training and testing activities, as described under Alternative 2, would have no effect on ESA-listed Hawaiian petrels, short-tailed albatrosses, Newell's shearwaters. This determination is consistent with the previous consultation between the Navy and USFWS for activities described in the 2015 MITT Final EIS/OEIS.

Under the MBTA regulations applicable to military readiness activities (50 CFR Part 21), the impacts from explosives stressors during training and testing activities using explosives described under Alternative 2 would not result in a significant adverse effect on populations of the great frigatebird, masked booby, or other marine bird populations.

3.6.2.2.3 Impacts from Explosive Stressors Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Explosive stressors as listed above would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer explosive stressors within the marine environment where Navy activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for impacts on marine birds from explosive stressors, but would not measurably improve the overall distribution or abundance of marine birds.

3.6.2.3 Energy Stressors

The energy stressors that may impact marine birds include (1) in-air electromagnetic devices and (2) high-energy lasers. However, as discussed in Section 3.0.4.3 (Energy Stressors), in-air electromagnetic energy would be widely dispersed throughout the Study Area, but more concentrated in portions of the Study Area near ports, naval installations, and range complexes. Because these stressors are operated at power levels, altitudes, and distances from people and animals to ensure that energy received is well below levels that could disrupt behavior or cause injury and because most in-air electromagnetic energy is reflected by water, in-air electromagnetic energy would not impact birds and is not analyzed further in this section.

Since the publication of the 2015 MITT Final EIS/OEIS, additional information has become available that improves understanding of how in-air electromagnetic devices (such as radar) may impact marine birds. This new information is included in this SEIS/OEIS. Studies conducted on in-air electromagnetic sensitivity in birds have typically been associated with land, and little information exists specifically on seabird response to in-air electromagnetic changes at sea. Based on these studies, in-air electromagnetic effects can be categorized as thermal (i.e., capable of causing damage by heating tissue) or non-thermal. Thermal effects are most likely to occur when near high-power systems. Should such effects occur, they would likely cause birds to temporarily avoid the area receiving the electromagnetic radiation until the stressor ceases (Manville, 2016). Currently, questions exist about far-field, non-thermal effects from low-power, in-air electromagnetic devices. Manville (2016) performed a literature review of this topic. Although findings are not always consistent, Manville (2016) reported that several peer-reviewed studies have shown non-thermal effects can include (1) affecting behavior by preventing birds from using their magnetic compass, which may in turn affect migration; (2) fragmenting the DNA of reproductive cells, decreasing the reproductive capacity of living organisms; (3) increasing the permeability of the blood-brain barrier; (4) other behavioral effects; (5) other molecular, cellular, and metabolic changes; and (6) increasing cancer risk.

Many bird species return to the same stopover, wintering, and breeding areas every year and often follow the exact same or very similar migration routes (Akesson & Hedenstrom, 2007). However, ample evidence exists that displaced birds can successfully reorient and find their way when one or more cues are removed. For example, Haftorn et al. (1988) found that after removal from their nests and release into a different area, snow petrels (*Pagodrama nivea*) were able to successfully navigate back to their nests even when their ability to smell was removed. Furthermore, Wiltschko et al. (2011) and Wiltschko and Wiltschko (2005) report that electromagnetic pulses administered to birds during an experimental study on orientation do not deactivate the magnetite-based receptor mechanism in the upper beak altogether but instead cause the receptors to provide altered information, which in turn causes birds to orient in different directions. However, these impacts were temporary, and the ability of the birds to correctly orient themselves eventually returned.

Given (1) the information provided above; (2) the dispersed nature of Navy training and testing activities at sea; (3) the relatively small area around an emitting source that experiences high power

electromagnetic pulses; and (4) the relatively low-level and dispersed use of these systems at sea, the following conclusions are reached:

- The chance that in-air electromagnetic devices would cause thermal damage to an individual marine bird is extremely low.
- It is possible, although unlikely, that some marine bird individuals would be exposed to levels of electromagnetic radiation that would cause discomfort, in which case they would likely avoid the immediate vicinity of testing and training activities.
- The strength of any avoidance response would decrease with increasing distance from the in-air electromagnetic device.
- No long-term or population-level impacts would occur.

There is only one new activity involving an energy stressor (i.e., high-energy lasers) that differs from activities with energy stressors that were previously analyzed in the 2015 MITT Final EIS/OEIS. Use of low-energy lasers was covered in the 2015 MITT Final EIS/OEIS in Section 3.0.5.2.2.3 (Lasers), but high-energy laser weapons were not part of the proposed action in the 2015 MITT Final EIS/OEIS. The use of high-energy lasers represents a new substressor used in an existing activity in this SEIS/OEIS. As discussed in this SEIS/OEIS, Section 3.0.4.3.2.2 (High-Energy Lasers), high-energy lasers are designed to disable surface targets, rendering them immobile. The primary concern is the potential for a marine bird to be struck with the laser beam at or near the water's surface, where extended exposure could result in injury or death due to traumatic burns from the beam.

Marine birds could be exposed to a laser only if they flew between the source and the target, or if the beam missed the target and a bird happened to be in the line of fire. Should the laser strike the sea surface, individual sea birds at or near the surface could be exposed. Because laser platforms are typically helicopters and ships, marine birds at sea would likely transit away or submerge in response to other stressors, such as ship or aircraft noise, although some marine birds may not exhibit a response to an oncoming vessel or aircraft, increasing the risk of contact with the laser beam. High-energy laser activities would only occur in open ocean locations (not close to land areas).

3.6.2.3.1 Impacts from High-Energy Lasers Under Alternative 1

Under Alternative 1, the number of proposed activities involving the use of high-energy lasers is shown in Table 3.0-10. High-energy lasers is a new substressor that was not analyzed in the 2015 MITT Final EIS/OEIS. As discussed above, impacts on marine birds from energy stressors should not be expected to occur.

A direct strike of a marine bird at the water's surface or within the beam path is extremely unlikely, and potential impacts on ESA-listed marine bird species are negligible. Therefore, the conclusions for ESA-listed marine bird species and other marine bird species protected by the MBTA included in the 2015 MITT Final EIS/OEIS remain valid.

During section 7 ESA consultation between the Navy and USFWS, the Navy determined that the activities described in the 2015 MITT Final EIS/OEIS would have no effect on the ESA-listed Hawaiian petrel, short-tailed albatross, or Newell's shearwaters.

Pursuant to the ESA, the use of high-energy lasers during training and testing activities, as described under Alternative 1, would have no effect on ESA-listed Hawaiian petrels, short-tailed albatrosses, Newell's Townsend's shearwaters. This determination is consistent with the previous consultation between the Navy and USFWS for activities described in the 2015 MITT Final EIS/OEIS.

Under the MBTA regulations applicable to military readiness activities (50 CFR Part 21), the impacts from energy stressors during training and testing activities using high-energy lasers described under Alternative 1 would not result in a significant adverse effect on populations of the great frigatebird, masked booby, or other marine bird populations.

3.6.2.3.2 Impacts from High-Energy Lasers Under Alternative 2 (Preferred Alternative)

Under Alternative 2, the use of high-energy lasers would increase as compared to Alternative 1 (Table 3.0-10), but there would be no change regarding the impact conclusions for energy stressors as summarized above under Alternative 1 and as presented in the 2015 MITT Final EIS/OEIS. Therefore, impacts on marine birds under Alternative 2 from energy stressors, including high-energy lasers, should not be expected to occur.

Pursuant to the ESA, the use of high energy lasers during training and testing activities, as described under Alternative 2, would have no effect on ESA-listed Hawaiian petrels, short-tailed albatrosses, Newell's shearwaters. This determination is consistent with the previous consultation between the Navy and USFWS for activities described in the 2015 MITT Final EIS/OEIS.

Under the MBTA regulations applicable to military readiness activities (50 CFR Part 21), the impacts from energy stressors during training and testing activities using high-energy lasers described under Alternative 2 would not result in a significant adverse effect on populations of the great frigatebird, masked booby, or other marine bird populations.

3.6.2.3.3 Impacts from High-Energy Lasers Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Energy stressors as listed above would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities. Discontinuing the training and testing activities would result in fewer energy stressors within the marine environment where Navy activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for impacts on marine birds from energy stressors, but would not measurably improve the overall distribution or abundance of marine birds.

3.6.2.4 Physical Disturbance and Strike Stressors

The physical disturbance and strike stressors that may impact marine birds include (1) aircraft and aerial targets, (2) vessels and in-water devices, (3) military expended materials, and (4) wildfires on FDM. For activities occurring at sea, the use of aircraft and aerial targets, vessels and in-water devices, and military expended materials would decrease under this SEIS/OEIS (Tables 3.0-11 through 3.0-17, and Table 3.0-20), with the exception of increased small caliber munitions use. Small-caliber munitions are inert, are meant to be aimed at targets, and are not long-range weapons. As a result, marine birds are extremely unlikely to be struck by expended small caliber munitions. Military expended materials would increase for training activities occurring on FDM. For the purposes of this SEIS/OEIS, only activities that

occur on or over FDM and activities that would occur in the open ocean environment that have changed since the publication of the 2015 MITT Final EIS/OEIS are discussed in this section.

Physical disturbances may elicit short-term behavioral or physiological responses such as alert response, startle response, cessation of feeding, fleeing the immediate area, and a temporary increase in heart rate. These disturbances can also result in abnormal behavioral, growth, or reproductive impacts in nesting birds and can cause foraging and nesting birds to flush from or abandon their habitats or nests. Aircraft strikes often result in bird mortalities or injuries.

Physical disturbance on land may induce erosion, either from loosening of rock and soil from direct impacts (which facilitates transport of material by wind and rain) or from wildfires ignited by explosions (see Section 3.6.3.3.5, Impacts from Wildfires, in the 2015 MITT Final EIS/OEIS). Military use of FDM may contribute to ongoing soil disturbance and erosion from natural causes. FDM is comprised of highly weathered limestone overlain by a thin layer of clay soil (U.S. Department of the Navy, 2013b). Ordnance use, particularly within Impact Areas 2 and 3 (where explosive munitions use is permitted), would dislodge sediments that may potentially wash into nearshore waters of FDM. In addition to natural wind and water erosion (including high-energy typhoon events), erosion caused by ordnance use would contribute to increased turbidity and siltation of habitats used by marine bird prey species.

Section 3.6.3.3.1 (Impacts from Aircraft and Aerial Targets) in the 2015 MITT Final EIS/OEIS discusses the potential impacts on birds from collisions with fixed-wing aircraft, helicopters, and aerial targets. Aircraft and aerial target strikes could occur during training and testing activities that use aircraft, particularly in nearshore areas, where birds are more concentrated in the Study Area. Training and testing activities where aircraft are used typically occur further offshore; however, increased use of FDM may increase the potential for aircraft strike of birds. Therefore, for the purposes of this SEIS/OEIS, only the use of aircraft related to FDM training activities are discussed below under the alternatives analysis for birds for this stressor category.

3.6.2.4.1 Impacts from Physical Disturbance and Strike Stressors Under Alternative 1

Under Alternative 1, physical disturbance and strike stressors associated with training and testing activities would decrease in comparison to the 2015 MITT Final EIS/OEIS (Tables 3.0-12 through 3.0-17, 3.0-19), assuming the dismissal of small-caliber munitions use for the reasons noted above. Under Alternative 1, there would be increases in the numbers of large-caliber non-explosive practice munitions (Table 3.0-14) and the number of targets expended at sea (Table 3.0-17), but overall there would be a decrease in the number of combined physical disturbance and strike stressors on marine birds. Consistent with the conclusions provided in the 2015 MITT EIS/OEIS, impacts on marine birds from physical disturbance and strike stressors are not expected to occur.

On FDM, marine birds that nest and roost on the island would be exposed to military expended materials resulting from explosive munitions and non-explosive practice munitions. Explosive munitions increase the potential for a marine bird (or nest) to be struck because of fragments dispersed throughout the blast zone.

As shown in Table 3.6-1, there would be an increase in the number of training events using FDM as a training location or target, with an increase in the number of munitions items expended on FDM (see Table 3.6-2).

Taken together, the increase in the number of training events per year or the amount of ordnance used during events would result in an increase in the amount of NEW expended on FDM each year (see Table

3.6-3). Although the amount of increased NEW is negligible (0.22–0.39 percent, depending on the NEW range of various munition types), the potential exposure to physical disturbance and strike stressors associated with ordnance use would increase under Alternative 1 compared to what was analyzed previously in the MITT Final EIS/OEIS. Factors that limit the potential for additional adverse impacts from physical disturbance and strike, however, include maintaining the same ordnance type and targeting restrictions included as part of the 2015 MITT Final EIS/OEIS. All ordnance expended on FDM would target existing impact zones, with the same ordnance restrictions imposed on all FDM activities and with the same avoidance and minimization measures in place (see Section 5.5, Terrestrial Mitigation Measures to be Implemented; and Table 5.5-1). Therefore, the increases in ordnance use on FDM shown in Tables 2.5-1 and 2.5-2 do not appreciably change the impact conclusions presented in the 2015 MITT Final EIS/OEIS. The conclusions for ESA-listed marine bird species and other marine bird species protected by the MBTA included in the 2015 MITT Final EIS/OEIS remain valid.

During section 7 ESA consultation between the Navy and USFWS, the Navy determined that the activities described in the 2015 MITT Final EIS/OEIS would have no effect on the ESA-listed Hawaiian petrel, short-tailed albatross, or Newell's shearwater.

Pursuant to the ESA, training and testing activities that use aircraft and aerial targets, as described under Alternative 1, would have no effect on ESA-listed Hawaiian petrels, short-tailed albatrosses, Newell's shearwaters. This determination is consistent with the previous consultation between the Navy and USFWS for activities described in the 2015 MITT Final EIS/OEIS.

Under the MBTA regulations applicable to military readiness activities (50 CFR Part 21), the impacts from physical disturbance and strike stressors during training and testing activities described under Alternative 1 would not result in a significant adverse effect on populations of the great frigatebird, masked booby, or other marine bird populations.

3.6.2.4.2 Impacts from Physical Disturbance and Strike Stressors Under Alternative 2 (Preferred Alternative)

Under Alternative 2, physical disturbance and strike stressors associated with training and testing activities would decrease in comparison to the 2015 MITT Final EIS/OEIS (Tables 3.0-12 through 3.0-17, 3.0-19) assuming the dismissal of small-caliber munitions use for the reasons noted above. Under Alternative 2, there would be increases in the numbers of large-caliber non-explosive practice munitions (Table 3.0-14) and the number of targets expended at sea (Table 3.0-17), but overall there would be a decrease in the number of combined physical disturbance and strike stressors on marine birds. Consistent with the conclusions provided in the 2015 MITT EIS/OEIS, impacts on marine birds from physical disturbance and strike stressors are not expected to occur.

On FDM under Alternative 2, there would be an increase in the number of training events using FDM as a training location or target (see Table 3.6-1), with an increase in the number of munitions items expended on FDM (see Table 3.6-2) compared to what was analyzed previously in the MITT Final EIS/OEIS and under Alternative 1.

Taken together, the increase in the number of training events per year or the amount of ordnance used during events would result in an increase in the amount of NEW expended on FDM each year (see Table 3.6-3). Although the amount of increased NEW is negligible (0.35–0.6 percent, depending on the NEW range of various munition types), the potential exposure to stressors associated with ordnance use would increase under Alternative 2 compared to what was analyzed previously in the MITT Final EIS/OEIS. Under Alternative 2, Naval Surface Firing Exercise events would expend more large-caliber

projectiles, thereby increasing the NEW expended under Alternative 2 compared to Alternative 1. Factors that limit the potential for additional adverse impacts, however, include maintaining the same ordnance type and targeting restrictions included as part of the 2015 MITT Final EIS/OEIS. All ordnance expended on FDM would target existing impact zones, with the same ordnance restrictions imposed on all FDM activities and with the same avoidance and minimization measures in place (see Section 5.5, Terrestrial Mitigation Measures to be Implemented; and Table 5.5-1). Therefore, the increases in ordnance use on FDM shown in Tables 2.5-1 and 2.5-2 do not appreciably change the impact conclusions presented in the 2015 MITT Final EIS/OEIS. The conclusions for ESA-listed marine bird species and other marine bird species protected by the MBTA included in the 2015 MITT Final EIS/OEIS remain valid.

Pursuant to the ESA, training and testing activities that use aircraft and aerial targets, as described under Alternative 2, would have no effect on ESA-listed Hawaiian petrels, short-tailed albatrosses, Newell's shearwaters. This determination is consistent with the previous consultation between the Navy and USFWS for activities described in the 2015 MITT Final EIS/OEIS.

Under the MBTA regulations applicable to military readiness activities (50 CFR Part 21), the impacts from physical disturbance and strike stressors during training and testing activities described under Alternative 2 would not result in a significant adverse effect on populations of the great frigatebird, masked booby, or other marine bird populations.

3.6.2.4.3 Impacts from Physical Disturbance and Strike Stressors Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Physical disturbance and strike stressors would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer physical disturbance and strike stressors within the marine environment where Navy activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for physical disturbance and strike impacts on marine birds, but would not measurably improve the overall distribution or abundance of marine birds.

3.6.2.5 Ingestion Stressors

As discussed in Section 3.6.3.4 (Ingestion Stressors) of the 2015 MITT Final EIS/OEIS, a variety of ingestible materials may be released into the marine environment by training and testing activities. Types of materials that could become ingestion stressors (military expended materials – munitions and military expended materials other than munitions) for marine birds during training and testing activities in the Study Area include non-explosive practice munitions (small and medium caliber), fragments from high-explosive munitions, fragments from targets, chaff, plastic end caps from chaff cartridges, the plastic compression pads, end caps from pistons and flares, and small decelerators/parachutes. Ingestion stressors would decrease with the exception of increased small-caliber munitions use (Table 3.0-14, Table 3.0-15, Tables 3.0-25 through 3.0-26). However, small-caliber munitions are inert, small in size, do not resemble prey items, and end up as part of the seafloor where they are unlikely to be encountered by marine birds. The number of munitions and explosive munitions fragments that an individual marine bird could encounter would generally be low, based on the patchy distribution of both the munitions and open water feeding habitats of marine birds. In addition, it is assumed an animal

would not ingest every munition or munition fragment it encountered, and if a munition or munition fragment were ingested, an animal may attempt to reject it when it realizes the item is not food.

3.6.2.5.1 Impacts from Ingestion Stressors Under the Alternative 1

Under Alternative 1, ingestion stressors would decrease, with the exception of increased small-caliber munitions use (Table 3.0-14, Table 3.0-15, Tables 3.0-25 through 3.0-26). For the reasons noted above, the Navy has determined that potential impacts from ingestion stressors would not be substantially different from the 2015 MITT Final EIS/OEIS. Military expended materials would be only a minute portion of the floating debris that marine birds could encounter and accidently ingest. While military expended materials may be a contributing factor to the harmful effects of manmade debris on some marine birds, an individual military expended material would not negatively impact a marine bird. The overall likelihood that individual birds would be negatively impacted by ingestion of military expended materials in the Study Area under Alternative 1 is considered low, but not discountable. Population-level effects would be very unlikely given the relatively small quantities and limited persistence of military expended materials in habitats where birds are most likely to forage. Because of the extreme low likelihood of geographic or temporal overlap with training and testing activities with ESA-listed marine birds, potential ingestion of expended materials by ESA-listed marine birds is considered negligible. Therefore, the analysis from the 2015 MITT Final EIS/OEIS remains valid.

Pursuant to the ESA, potential ingestion stressors introduced by training and testing activities under Alternative 1 would have no effect on ESA-listed Hawaiian petrels, short-tailed albatrosses, Newell's shearwaters. This determination is consistent with the previous consultation between the Navy and USFWS for activities described in the 2015 MITT Final EIS/OEIS.

Under the MBTA regulations applicable to military readiness activities (50 CFR Part 21), potential ingestion stressors introduced by training and testing activities under Alternative 1 would not result in a significant adverse effect on populations of the great frigatebird, masked booby, or other marine bird populations.

3.6.2.5.2 Impacts from Ingestion Stressors Under Alternative 2 (Preferred Alternative)

Under Alternative 2, ingestion stressors (military expended materials – munitions and military expended materials other than munitions) would decrease under this SEIS/OEIS in comparison to the ongoing activities, with the exception of increased small-caliber munitions use (Table 3.0-14, Table 3.0-15, and Tables 3.0-25 through 3.0-26). Under Alternative 2, increases as compared to Alternative 1 do not change the impact conclusions for ingestion stressors as summarized above under Alternative 1 and as presented in the 2015 MITT Final EIS/OEIS. Therefore, impacts on marine birds from ingestion of military expended materials under Alternative 2 would be negligible.

Pursuant to the ESA, potential ingestion stressors introduced by training and testing activities under Alternative 2 would have no effect on ESA-listed Hawaiian petrels, short-tailed albatrosses, Newell's shearwaters. This determination is consistent with the previous consultation between the Navy and USFWS for activities described in the 2015 MITT Final EIS/OEIS.

Under the MBTA regulations applicable to military readiness activities (50 CFR Part 21), potential ingestion stressors introduced by training and testing activities under Alternative 2 would not result in a significant adverse effect on populations of the great frigatebird, masked booby, or other marine bird populations.

3.6.2.5.3 Impacts from Ingestion Stressors Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Ingestion stressors would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer ingestion stressors within the marine environment where Navy activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for ingestion impacts on marine birds, but would not measurably improve the overall distribution or abundance of marine birds.

3.6.2.6 Secondary Stressors (impacts on habitat, impacts on prey availability)

The potential for secondary stressors, defined as potential impacts on habitat and prey availability, to impact marine bird species was analyzed in Section 3.6.3.5 (Secondary Stressors) of the 2015 MITT Final EIS/OEIS. Training and testing activities analyzed in this SEIS/OEIS would not introduce additional secondary stressors or change the impacts of secondary stressors on marine bird species from what was analyzed previously in the 2015 MITT Final EIS/OEIS.

3.6.2.7 Endangered Species Act Determinations

Since the publication of the 2015 MITT Final EIS/OEIS, there have been no updates to the regulatory status, life history information, or species-specific threats that would alter the analysis from the 2015 MITT Final EIS/OEIS for the short-tailed albatross, Hawaiian petrel, or Newell's shearwater. As such, the description regarding these marine bird species presented in the 2015 MITT Final EIS/OEIS remains valid. Because of the limited period of time that ESA-listed marine bird species would be within the Study Area and the extreme unlikelihood that these birds would be subject to stressors generated by training and testing activities within the Study Area, the Navy and the USFWS have not included these species in past at-sea training and testing consultations within the Study Area (U.S. Fish and Wildlife Service, 2010, 2015). Similar to these past consultations, the activities proposed in Chapter 2 (Description of Proposed Action and Alternatives) of this SEIS/OEIS would have no effect on ESA-listed marine birds.

3.6.3 Migratory Bird Treaty Act

The Navy has conducted an analysis of the potential impacts of increasing the number of events, munitions, and NEW expended on FDM. Taken together with the statistical analysis of bird trends on FDM described above in Section 3.6.2 (Environmental Consequences) and determinations that no significant population impacts would occur, the small increases in events, munitions numbers, and expended NEW on FDM proposed in this SEIS/OEIS would not significantly impact bird populations, as defined in the MBTA regulations applicable to military readiness activities (50 CFR Part 21). While this determination is applicable to all marine birds that occur in the Study Area, the Navy carried out a focused analysis for marine birds known to breed on FDM (see the discussion for population-level analysis in Section 3.6.2, Environmental Consequences). Pursuant with the Department of Defense's obligations under 50 CFR Part 21, the Department of Defense will continue to implement training restrictions on FDM (see Section 5.5, Terrestrial Mitigation Measures to be Implemented) and monitoring of bird populations on FDM.

3.6.4 Public Comments

The public raised a number of issues during the scoping period in regard to marine birds. The issues are summarized in the list below. Comments received from the public during the Draft SEIS/OEIS commenting period related to marine birds are addressed in Appendix K (Public Comment Responses).

- **Public comments regarding potential impacts of marine bird species on FDM –** This SEIS/OEIS includes an analysis of potential impacts from the additional training activities proposed to occur at FDM. For acoustic stressors, Section 3.6.2.1.3 (Impacts from Aircraft Noise) and Section 3.6.2.1.4 (Impacts from Weapons Noise) include an analysis of how these stressor types may impact marine bird rookeries on FDM. For explosives stressors, Section 3.6.2.2 (Explosives Stressors [explosive shock wave and sound, explosive fragments]) includes an analysis of how the proposed increase in munitions for missile exercises and direct action training activities could impact marine birds on the island. Stressor categories within physical disturbance and strike stressors, such as potential strike impacts from aircraft and impacts from wildfires, also include an FDM-focused analysis. While assessing these potential impacts of activities proposed in this SEIS/OEIS, it is important to note that all of the activities would continue under the same targeting constraints as described in the 2015 MITT Final EIS/OEIS. Mitigation measures designed in cooperation with U.S. Fish and Wildlife Service personnel provide a level of protection for the northern end of the island (where booby colonies have persisted), while ordnance use is only allowed in designated impact zones (see Section 5.5, Terrestrial Mitigation Measures to be Implemented).
- **Public comments regarding the status of nesting birds on FDM –** This SEIS/OEIS has been updated to include recent published work that provides a statistical review of repeated marine bird surveys on FDM. Camp et al. (2016) analyzed marine bird survey data collected from aerial surveys from 1997 to 2014. As discussed in Section 3.6.1.7 (Rookery Locations and Breeding Activities within the Mariana Islands), there is some evidence that masked and red-footed booby populations on FDM have declined, while brown booby populations have increased, though none of these trends were statistically significant. The general conclusion is that all three species exhibited population fluctuations over time. These fluctuations, combined with the level of variability observed in the count data, precluded any definitive conclusions about long-term population trends (i.e., the data were non-significant) (Camp et al., 2016). This SEIS/OEIS also includes historical observations and more recent surveys, such as Lusk et al. (2000), to provide context for the trend data and statistical analyses of FDM marine bird populations. Aerial surveys are conducted more frequently over FDM than on-the-ground surveys, with the primary focus to monitor marine bird rookeries (namely, brown boobies, masked boobies, and red-footed boobies). These surveys are described in more detail, along with quantitative trend analysis of populations in Section 3.6.2.6.3 (Farallon de Medinilla) of the 2015 MITT Final EIS/OEIS. All of these studies are summarized and included the Joint Region Marianas Integrated Natural Resources Management Plan (U.S. Department of the Navy, 2019), which is shared with cooperating agencies (e.g., Guam Department of Agriculture Division of Aquatic and Wildlife Resources, Commonwealth of the Northern Mariana Islands Department of Land and Natural Resources Division of Fish and Wildlife, and USFWS Pacific Islands Fish and Wildlife Office).

3.7 Marine Vegetation

3.7.1 Affected Environment

The purpose of this section is to supplement the analysis of impacts on Marine Vegetation presented in the 2015 Mariana Islands Training and Testing (MITT) Final Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS) with new information relevant to proposed changes in training and testing activities conducted at sea and on Farallon de Medinilla (FDM). New information made available since the publication of the 2015 MITT Final EIS/OEIS is included below to better understand potential stressors and impacts on Marine Vegetation resulting from training and testing activities. Comments received from the public during scoping related to marine vegetation are addressed in Section 3.7.3 (Public Comments). Comments received from the public during the Draft Supplemental EIS (SEIS)/OEIS commenting period related to marine vegetation are addressed in Appendix K (Public Comment Responses).

3.7.1.1 General Threats

There is no new information on threats to marine vegetation in the MITT Study Area that would change the conclusions from the 2015 MITT Final EIS/OEIS.

3.7.1.2 Marine Vegetation Groups

There is no new information on marine vegetation groups (phylum Cyanobacteria [blue-green algae], phylum Dinophyta [dinoflagellates], phylum Chlorophyta [green algae], phylum Heterokontophyta [brown algae], phylum Rhodophyta [red algae], and phylum Spermatophyta [flowering plants]) that would change the basis of the conclusions from the 2015 MITT Final EIS/OEIS.

3.7.1.3 Seagrasses

There is no new information on seagrasses that would change the basis of the conclusions from the 2015 MITT Final EIS/OEIS.

3.7.1.4 Mangroves

There is no new information on mangroves that would change the basis of the conclusions from the 2015 MITT Final EIS/OEIS.

3.7.2 Environmental Consequences

The 2015 MITT Final EIS/OEIS considered training and testing activities that currently occur in the Study Area and considered potential stressors related to marine vegetation. With the exception of explosives, stressors analyzed are the same as those analyzed in the 2015 MITT Final EIS/OEIS. In the 2015 MITT Final EIS/OEIS, explosives were addressed under acoustic stressors; however, for purposes of this analysis, explosives are analyzed as a separate stressor. The following are stressors analyzed for marine vegetation from the 2015 MITT Final EIS/OEIS:

- Explosive (in-air explosions and in-water explosions)
- Physical disturbance and strike (vessels, in-water devices, military expended materials, and seafloor devices)
- Secondary stressors (impacts associated with sediments and water quality)

This section evaluates how and to what degree potential impacts on marine vegetation from stressors described in Section 3.0 (General Approach to Analysis) may have changed since the analysis presented

in the 2015 MITT Final EIS/OEIS was completed. Proposed training and testing activities, the number of times each activity would be conducted annually, and the locations within the Study Area where the activity would typically occur under each alternative are presented in Tables 2.4-1 and 2.4-2 in Chapter 2 (Description of Proposed Action and Alternatives). The tables also present the same information for activities described in the 2015 MITT Final EIS/OEIS so that the proposed levels of training and testing under this SEIS/OEIS can be easily compared.

The Navy conducted a review of federal and state regulations and standards relevant to marine vegetation and reviewed literature published since 2015 for new information that could inform the analysis presented in the 2015 MITT Final EIS/OEIS. The analysis presented in this section also considers standard operating procedures, which are discussed in Section 2.3.3 (Standard Operating Procedures) of this Final SEIS/OEIS, and mitigation measures that are described in Chapter 5 (Mitigation). The Navy implements these measures to avoid or reduce potential impacts on marine vegetation from stressors associated with training and testing activities.

3.7.2.1 Explosive Stressors

As stated in the 2015 MITT Final EIS/OEIS, the potential for an explosion to injure or destroy marine vegetation would depend on the amount of vegetation present, the number of munitions used, and their net explosive weight. In areas where marine vegetation and locations for explosions overlap, marine vegetation on the surface of the water, in the water column, or rooted in the seafloor may be impacted. Seafloor macroalgae and single-celled algae may overlap with underwater and sea surface explosion locations. If these vegetation types are near an explosion, only a small number of them are likely to be impacted. Much of the attached macroalgae grows on live hard bottom areas that would be mostly protected in accordance with Navy mitigation measures (see Chapter 5, Mitigation). Also, some seafloor macroalgae are resilient to high levels of wave action (Mach et al., 2007), which may aid in their ability to withstand underwater explosions that occur near them. Underwater explosions also may temporarily increase the turbidity (sediment suspended in the water) in nearby waters, incrementally reducing the amount of light available to marine vegetation. Reducing light availability decreases, albeit temporarily, the photosynthetic ability of marine vegetation.

Seagrasses may potentially be uprooted or damaged by sea surface or underwater explosions. Regrowth of seagrasses after uprooting can take up to 10 years (Dawes et al., 1997). Explosions may also temporarily increase the turbidity (sediment suspended in the water) in nearby waters, but the sediment would settle to pre-explosion conditions within a few hours to days. Sustained high levels of turbidity may reduce the amount of light that reaches vegetation, which it needs to survive. Seagrasses typically grow in waters that are sheltered from wave action, such as estuaries, lagoons, and bays (Phillips & Meñez, 1988), where most activities are not conducted. Detonations are unlikely to occur in areas with mangroves or sea grasses and would continue to occur in disturbed areas over the unvegetated seafloor such as the Agat Bay site, Piti, and Outer Apra Harbor sites.

3.7.2.1.1 Impacts from Explosive Stressors Under Alternative 1

Under Alternative 1, there would be an overall decrease in the number of explosives used in the Study Area during training and testing activities events compared to the number analyzed in the 2015 MITT Final EIS/OEIS (Table 3.0-7). Under Alternative 1, underwater detonations would increase for underwater demolition qualification/certification (Table 2.4-1). However, these activities would continue to occur in the same areas and would have no appreciable change in the impact analysis or

conclusions for explosive stressors as presented in the 2015 MITT Final EIS/OEIS. Therefore, the analysis in the 2015 MITT Final EIS/OEIS remains valid.

As described in the 2015 MITT Final EIS/OEIS, underwater explosions conducted for training and testing activities may destroy or remove marine vegetation. However, exposure to these detonations would be limited to the vicinity of the explosions. For example, the offshore underwater mine neutralization sites are located in areas with water depths that are unlikely for marine vegetation to occur. Underwater and surface explosions conducted for training and testing activities are not expected to pose a risk to seagrass because (1) the impact area of underwater explosions is very small relative to seagrass distribution and (2) the low number of charges reduces the potential for impacts.

Therefore, the use of explosives is not expected to impact the long-term survival, annual reproductive success, and lifetime reproductive success of marine vegetation.

3.7.2.1.2 Impacts from Explosive Stressors Under Alternative 2 (Preferred Alternative)

Under Alternative 2, the number of explosives used during training and testing activities would decrease compared to the numbers analyzed in the 2015 MITT Final EIS/OEIS and increase compared to Alternative 1 (Table 3.0-7). Under Alternative 2, increases in the number of underwater explosives would have no appreciable change on the impact conclusions for explosive stressors as summarized above under Alternative 1 and as presented in the 2015 MITT Final EIS/OEIS. Therefore, explosive impacts on marine vegetation under Alternative 2 would be negligible.

3.7.2.1.3 Impacts from Explosive Stressors Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Explosive stressors as listed above would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer explosive stressors within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for explosive impacts on marine vegetation, but would not measurably improve the overall distribution or abundance of marine vegetation.

3.7.2.2 Physical Disturbance and Strike Stressors

This section analyzes the potential impacts on marine vegetation of the various types of physical disturbance and strike stressors during training and testing activities within the Study Area. Three types of physical disturbance and strike stressors are evaluated for their impacts on marine vegetation, including (1) vessels and in-water devices, (2) military expended materials, and (3) seafloor devices.

The evaluation of the impacts of physical disturbance stressors on marine vegetation focuses on proposed activities that may cause vegetation to be damaged by an object that is moving through the water (e.g., vessels and in-water devices), or dropped to the seafloor (e.g., military expended materials, anchors). Not all activities are proposed throughout the Study Area. Wherever appropriate, specific geographic areas of potential impact are identified.

As described in the 2015 MITT Final EIS/OEIS, vessel disturbance of marine vegetation would be limited to floating marine algae. Vessel movements may disperse or injure algal mats. Because algal distribution

is patchy and mats may re-form following a disturbance, training and testing activities involving vessel movement would not impact the general health of marine algae.

3.7.2.2.1 Impacts from Physical Disturbance and Strike Stressors Under Alternative 1

Under Alternative 1, the number of proposed training and testing events involving vessel movements would increase from those presented in the 2015 MITT Final EIS/OEIS (Table 3.0-12). In contrast, the use of towed in-water devices (Table 3.0-13) would decrease. The decrease in the number of in-water devices is unlikely to change the impact conclusion presented in the 2015 MITT Final EIS/OEIS. As stated in the 2015 MITT Final EIS/OEIS, the impact of vessels and in-water devices on marine vegetation would remain inconsequential because of (1) the quick recovery of most vegetation types; (2) the short-term nature of most vessel movements and local disturbances of the surface water, with some temporary increase in suspended sediment in shallow areas; and (3) the deployment of in-water devices at depths where they would not likely come in contact with marine vegetation.

Under Alternative 1, the number of military expended materials used for training and testing activities that has the potential to impact marine vegetation would generally increase (see Tables 3.0-14 through 3.0-17). However, these increases are not expected to pose a risk to marine algae or seagrasses because (1) the relative coverage of marine algae in the Study Area is low, (2) new growth may result from marine algae exposure to military expended materials, (3) the impact area of military expended materials is very small relative to marine algae distribution, and (4) seagrass overlap with areas where the stressor occurs is very limited. In addition, as shown in Table 3.0-18, the total area of the seafloor that could be impacted by the use of military expended materials as proposed in this Supplemental EIS/OEIS would decrease from the amount analyzed in the 2015 MITT Final EIS/OEIS under Alternative 1. Based on these factors, potential impacts on marine algae and seagrass from military expended materials are not expected to result in detectable changes in their growth, survival, or propagation, and are not expected to result in population-level impacts.

Under Alternative 1, the number of seafloor devices used in shallow-water habitats during training and testing activities would decrease slightly from the number presented in the 2015 MITT Final EIS/OEIS (Table 3.0-19). Seafloor devices would pose a negligible risk to marine vegetation for the same reasons described above for military expended materials and no impacts on the long-term survival, reproductive success, and lifetime reproductive success would occur.

Therefore, physical disturbance and strike impacts on marine vegetation under Alternative 1 would be negligible.

3.7.2.2.2 Impacts from Physical Disturbance and Strike Stressors Under Alternative 2 (Preferred Alternative)

Under Alternative 2, the combined number of proposed training and testing events involving vessels and in-water devices (Table 3.0-12 and Table 3.0-13) would decrease slightly from those presented in the 2015 MITT Final EIS/OEIS. Military expended materials (Table 3.0-14, Table 3.0-15, and Table 3.0-16) combined would increase, and seafloor devices (Table 3.0-19) would decrease slightly from the number in the 2015 MITT Final EIS/OEIS. Increases in some physical disturbance and strike stressors such as military expended materials could increase the impact risk on marine vegetation but does not appreciably change the analysis or impact conclusions presented in the 2015 MITT Final EIS/OEIS and those summarized above under Alternative 1.

Therefore, physical disturbance and strike impacts on marine vegetation under Alternative 2 would be negligible.

3.7.2.2.3 Impacts from Physical Disturbance and Strike Stressors Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Physical disturbance and strike stressors as listed above would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer physical disturbance and strike stressors within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for physical disturbance and strike impacts on marine vegetation, but would not measurably improve the overall distribution or abundance of marine vegetation.

3.7.2.3 Secondary Stressors

Stressors from Navy training and testing activities could pose secondary or indirect impacts on marine vegetation via habitat, sediment, or water quality. Potential impacts on marine vegetation exposed to secondary stressors could occur indirectly through sediments and water quality. Components of these stressors that could pose indirect impacts include (1) explosives and byproducts; (2) metals; (3) chemicals; and (4) other materials such as targets, chaff, and plastics.

Section 3.1 (Sediments and Water Quality) considered the impacts on marine sediments and water quality from explosives and explosive byproducts, metals, chemicals other than explosives, and other materials (marine markers, flares, chaff, targets, and miscellaneous components of other materials). As stated in the 2015 MITT Final EIS/OEIS, one example of a localized impact on marine vegetation associated with water quality impacts could be the increase of cyanobacteria associated with munitions deposits in marine sediments. Cyanobacteria may proliferate when the iron is introduced to the marine environment, and this proliferation can affect surrounding habitats by releasing toxins or stimulating the growth of nuisance species (Schils, 2012). Introducing iron into the marine environment from munitions or infrastructure is not associated with red tide events; rather, these harmful events are more associated with natural causes (e.g., upwellings) and the effects of human activities (e.g., agricultural runoff and other coastal pollution) (Hayes et al., 2007; Whitton & Potts, 2008).

Sediments entering the nearshore environment from FDM as a result of natural processes or explosives associated with strike warfare could cause temporary water quality impacts, some of which may be in foraging areas used by marine organisms. By limiting the location and extent of target areas, along with the types of ordnance allowed within specific impact areas, the military minimizes the potential for soil transport and, thus, water quality impacts. Erosion as a result of training activities at FDM may contribute to deposition of soils into the nearshore areas of FDM, causing increased turbidity. Turbidity can impact vegetation communities by reducing the amount of light that reaches these organisms. The impacts of explosive byproducts on sediment and water quality would be indirect, short term, and local. Explosive ordnance could loosen the soil on FDM and runoff from surface drainage areas containing soil, and explosive byproducts could contaminate sediments and the surrounding ocean water.

3.7.3 Public Comments

The public raised a number of issues during the scoping period in regard to marine vegetation. The issues are summarized in the list below. Comments received from the public during the Draft SEIS/OEIS

commenting period related to marine vegetation are addressed in Appendix K (Public Comment Responses).

- **Direct impacts on seagrass from sedimentation around FDM and military expended materials as marine debris –** Direct impacts on seagrass from sedimentation around FDM occur due to explosive stressors. Explosives may temporarily increase the turbidity (sediment suspended in the water) of nearby waters, but the sediment would settle to pre-explosion conditions within a short amount of time (e.g., a few hours to days). Sustained high levels of turbidity may reduce the amount of light that reaches vegetation, which it needs to survive. This scenario is not likely given the low number of explosions planned in areas with seagrass. Potential impacts on seagrass from military expended materials are not expected to result in detectable changes in their growth, survival, or propagation, and are not expected to result in population-level impacts. See Section 3.7.2.1 (Explosive Stressors) for further analysis of increased turbidity or sedimentation on marine vegetation including seagrasses in the Study Area including FDM. Military expended materials are discussed in Section 3.7.2.2 (Physical Disturbance and Strike Stressors) as a cause of physical disturbance and strike to marine vegetation.
- **Request survey of all seagrass beds in the Study Area and monitoring of the seagrass beds –** The analysis of impacts on marine vegetation, including seagrasses, concluded that increased turbidity may be caused by items used in training and testing activities; under the standard operating procedures, the Navy avoids the seafloor to the greatest extent practicable. Additionally, activities that have a greater potential to impact the seafloor, such as amphibious assaults, are conducted at high tide to limit such interactions. Anchorages are also scheduled to occur in specific locations, mainly areas that lack vegetation and that have been previously disturbed. Therefore, serious damage is not anticipated, and survey or mitigation measures are not warranted. In addition, the 2015 MITT Final EIS/OEIS includes maps showing areas of marine vegetation in Section 3.7 (Marine Vegetation).
- **Impact of unexploded ordnance on marine species –** Potential impacts on marine vegetation from unexploded ordnance are not expected to result in detectable changes in their growth, survival, or propagation, and are not expected to result in population-level impacts. The impact of unexploded ordnance to marine species, specifically to marine vegetation, is discussed in Section 3.7.2.2 (Physical Disturbance and Strike Stressors) as a cause of physical disturbance and strike to marine vegetation.
- **Impacts on marine species from chemical pollution and destruction of habitat –** The analysis concluded that neither state nor federal standards or guidelines for sediments or water quality would be violated as a result of the implementation of the proposed training and testing activities. Therefore, because these standards and guidelines are structured to protect human health and the environment, and the proposed activities do not violate them, no indirect impacts are anticipated on marine vegetation from the training and testing activities proposed in this SEIS/OEIS. Destruction of habitat is not anticipated to result from the implementation of training and testing activities proposed in this SEIS/OEIS. Impacts on marine species, specifically to marine vegetation from chemical pollution, is discussed in Section 3.7.2.5 (Secondary Stressors).
- **Impacts on marine species from the metals in the water (copper and lead) –** The analysis concluded that neither state nor federal standards or guidelines for sediments or water quality

would be violated as a result of the implementation of the proposed training and testing activities. Therefore, because these standards and guidelines are structured to protect human health and the environment, and the proposed activities do not violate them, no indirect impacts are anticipated on marine vegetation from the training and testing activities proposed in this SEIS/OEIS. Impacts on marine species, specifically on marine vegetation, from metals in the water (such as copper and lead) are discussed in Section 3.7.2.3 (Secondary Stressors).

- **Deposition and resuspension of sediments to Essential Fish Habitat (EFH) from training activities –** Both the 2015 MITT Essential Fish Habitat Assessment (EFHA) and the 2019 MITT Supplemental EFHA concluded that any impacts from explosives or physical disturbance and strike stressors that could cause deposition or resuspension of sediments would be short term and minimal.
- **Erosion and sedimentation impacting EFH –** The 2015 MITT EFHA concluded that any impacts from explosives or physical disturbance and strike stressors that could cause erosion and sedimentation would be short term and minimal.
- **Unexploded ordnance being triggered after use and directly impacting EFH –** Unexploded ordnance that explodes due to being triggered post training and testing would be considered an explosive stressor and the 2015 MITT EFHA concluded that the impacts on attached macroalgae from explosives used during training and testing would be minimal and temporary to short term throughout the Study Area. This analysis remains valid. Given the available information, the impact of explosives used during training and testing on submerged rooted vegetation beds would be minimal.

3.8 Marine Invertebrates

3.8.1 Affected Environment

The purpose of this section is to supplement the analysis of impacts on marine invertebrates presented in the 2015 Mariana Islands Training and Testing (MITT) Final Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS) with new information relevant to proposed changes in training and testing activities conducted at sea and on Farallon De Medinilla (FDM). New information made available since the publication of the 2015 MITT Final EIS/OEIS is included below to better understand potential stressors and impacts on marine invertebrates resulting from training and testing activities. Comments received from the public during scoping related to marine invertebrates are addressed in Section 3.8.3 (Public Comments). Comments received from the public during the Draft Supplemental EIS (SEIS)/OEIS commenting period related to marine invertebrates are addressed in Appendix K (Public Comment Responses).

Sensitive habitats in the Study Area include deep sea hydrothermal vents and coral reefs. As discussed in Section 3.3 (Marine Habitats), hydrothermal vents in the Study Area are located in the Mariana Archipelago (U.S. Fish and Wildlife Service, 2012). These areas support marine biological communities that are dependent on basalt rock foundations, unlike those throughout the remainder of the Pacific. Hydrothermal vent communities are typically low in species composition, but high in abundance of those few species. Deep-water benthic communities, including hydrothermal vents, include animals that have developed symbiotic relationships with chemosynthetic bacteria, such as tubeworms, shrimp, and mussels, as well as other animals like snails, anemones, and squat lobsters (Glickson et al., 2017) and take extremely long to recover from disturbances (Simon-Lledo et al., 2019).

Coral reefs in the Study Area are threatened by unsustainable fishing practices, climate change, land-based sources of pollution, overuse, and lack of enforcement (National Oceanic and Atmospheric Administration, 2018a). Coral reefs within the Mariana Islands are moderately impacted, and their overall condition is considered fair. Coral reefs in the northern islands are in good condition, while the southern islands such as Saipan had the most diverse types of coral reefs and associated habitats in the Mariana Islands (National Oceanic and Atmospheric Administration, 2018a). In contrast, coral reef condition in Tinian and Rota are considered impacted. While these conditions reflect data collected through summer 2017, very recent data suggest coral reef bleaching has resulted in severe impacts, with up to 90 percent loss for some branching coral species occurring around Saipan and Tinian (National Oceanic and Atmospheric Administration, 2018a). It is unclear what the impact of these bleaching events will be on all reefs of the Mariana Islands, but preliminary information suggests widespread loss across the archipelago.

Smith and Marx (2016) presented results from dive surveys in waters surrounding the live-fire range off FDM that provide qualitative observations of water and sediment quality and noted the condition of the biological resources (see Section 3.1, Sediments and Water Quality). A moderate bleaching event was noted in 2007, and a barnacle infestation was noted in 2012 (Smith et al., 2013). The bleaching event was regional and extended from southern Japan through the Mariana Islands and south through waters surrounding Palau. Subsequent surveys observed soft and fire corals had recovered completely; 75 percent of the stony corals had recovered by 2008 and the coral fauna at FDM were observed to be healthy and robust (Smith & Marx, 2009, 2016). The nearshore physical environment and basic habitat types at FDM have remained unchanged over the 13 years of survey activity. These conclusions are based on (1) a limited amount of physical damage, (2) very low levels of partial mortality and disease

(less than 1 percent of all species observed), (3) absence of excessive mucus production, (4) good coral recruitment, (5) complete recovery by 2012 of the 2007 bleaching event, and (6) a limited number of macrobioeroders and an absence of invasive crown of thorns starfish (*Acanthaster planci*).

A recent coral reef survey by Carilli et al. (2018) at FDM verified Endangered Species Act (ESA)-listed corals, quantified coral reef health, and compiled observations of ordnance impacts. Percent coral cover from these surveys is presented in Figure 3.8-1.

The survey results indicated that ESA-listed corals are present, but rare in waters of <20 meters (m) depth around FDM. Additionally, 77.3 percent of corals observed exhibited some form of bleaching, likely caused by regionally anomalous warm sea surface temperatures. Carilli et al. (2018) found little evidence of adverse impacts on coral from Navy training and testing, including the use of high-explosive bombs, and scleractinian coral growth occurred on a substantial percentage of ordnance items expended.

Guam's coral reefs are moderately impacted, and overall conditions are fair (National Oceanic and Atmospheric Administration, 2018b). Guam's reefs are struggling against threats such as pollution, overfishing, and climate change. Coral cover on Guam is generally similar to other southern Mariana Islands, but lower than the northern islands (Raymundo et al., 2016). Because coral distribution and coral cover on reefs is naturally patchy and heterogeneous, a single island-wide number is not a representative summary of the coral community. Long-term monitoring surveys conducted by the National Marine Fisheries Service's Pacific Assessment and Monitoring Program found approximately 10−15 percent coral cover overall, but the recent multi-year coral bleaching events have had variable consequences for the reef communities on Guam. For example, Raymundo et al. (2017) estimated a 53 percent decline in staghorn *Acropora* spp. on Guam. Of the 21 sites in the study, 6 are on Joint Region Marianas-administered submerged lands including 4 in Apra Harbor. The estimated mean mortality of staghorn *Acropora* spp. was 80 percent at Big Blue Shoals, 80 percent at Western Shoals, 30 percent at Dogleg, and 90 percent at Gab Gab (Raymundo et al., 2016). In the past several years, corals in Guam have been bleaching regularly each summer and recovery has been limited, leading to significant levels of coral mortality (Harvey, 2016; Raymundo et al., 2017).

Even though the new studies show variability in coral cover at FDM, including decreases in cover of some coral species off Guam, this information does not appreciably change the analysis presented in the 2015 MITT Final EIS/OEIS.

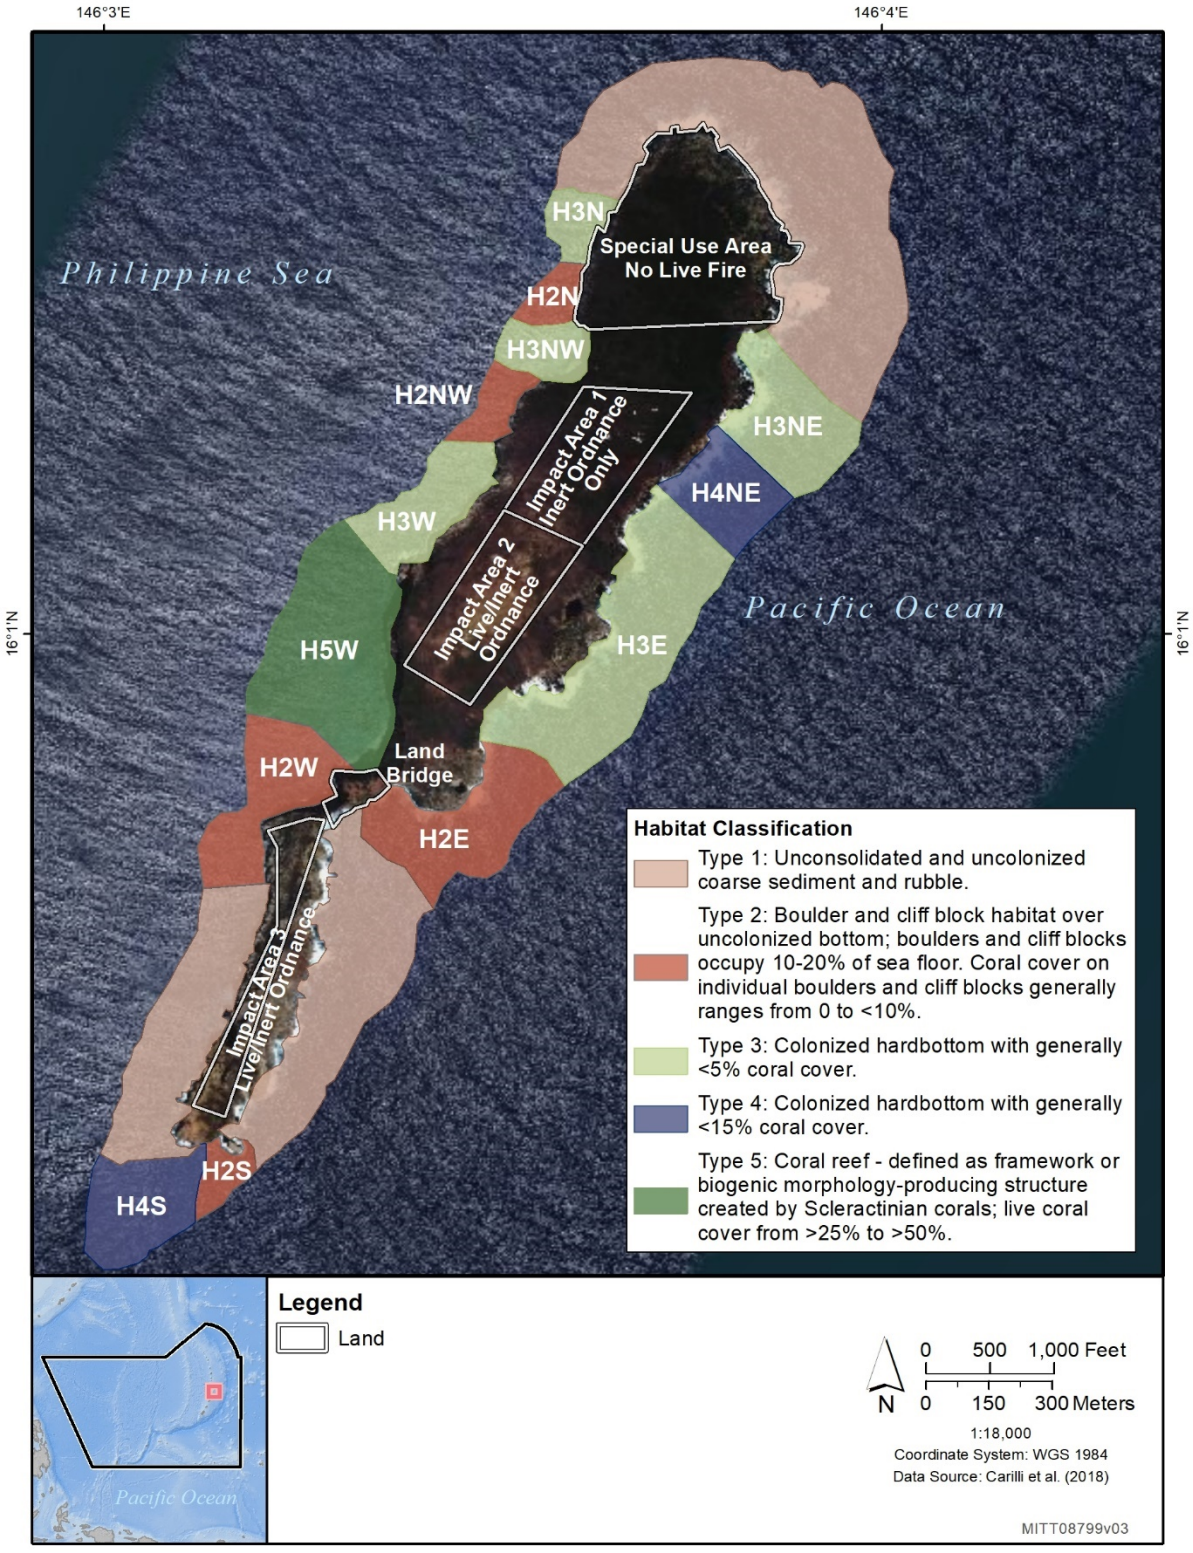

Figure 3.8-1: Percent Coral Cover and Habitat Types Around Farallon de Medinilla

3.8.1.1 Sound Sensing and Production

New studies on particle motion detection by Roberts et al. (2016) reinforces the finding that mechanical receptors on some invertebrates are found on various body parts. In addition, these structures are connected to the central nervous system and can detect some movements or vibrations that are transmitted through substrate (Edmonds et al., 2016). However, the addition of this new information does not appreciably change the information or analysis presented in the 2015 MITT Final EIS/OEIS.

3.8.1.2 General Threats

The health and abundance of marine invertebrates and general threats to coral reef systems are well documented and discussed in detail in the 2015 MITT Final EIS/OEIS. These threats include stress or damage by coastal development (Risk, 2009), impacts from inland pollution and erosion (Cortes and Risk 1985), overexploitation and destructive fishing practices (Jackson et al., 2001; Pandolfi et al., 2003), disease (Porter et al., 2001), predation, harvesting by the aquarium trade (Caribbean Fishery Management Council, 1994, 2016), anchors (Burke & Maidens, 2004), invasive species (Bryant et al., 1998; Galloway et al., 2009; National Marine Fisheries Service, 2010; Wilkinson, 2002), ship groundings (National Oceanic and Atmospheric Administration, 2010), oil spills (National Oceanic and Atmospheric Administration, 2010), marine debris (Lusher et al., 2016), disturbance by recreational activities at beaches, possibly human-made noise (Brainard et al., 2011; Vermeij et al., 2010), and global climate change, which includes impacts such as increases in sea surface temperature (van Hooidonk et al., 2016) and ocean acidification (Anthony, 2016; Hughes et al., 2003). Several studies suggest a direct link between declining water quality from increased runoff and sedimentation and coral reef health and bleaching (Ennis et al., 2016; Gailani et al., 2016; Nelson et al., 2016). Coral bleaching and bleaching of other invertebrates such as anemones, which occurs when symbiotic algae living in their tissues is expelled, is a stress response often tied to atypically high sea temperatures or changes in light availability but also can be attributed to nutrients, toxicants, and pathogens (National Oceanic and Atmospheric Administration, 2017). For example, toxicants such as oxybenzone and zinc and titanium oxide found in sunscreens and personal beauty products have been shown to induce severe and rapid coral bleaching due to the alteration of the symbiosis between coral and zooxanthellae (Corinaldesi et al., 2018; Downs et al., 2016).

3.8.1.3 Endangered Species Act-Listed Species

In 2014, the National Marine Fisheries Service (NMFS) published the Final Rule (79 Federal Register 53851) protecting 22 coral species under the Endangered Species Act (ESA), including the two corals (elkhorn and staghorn) listed as threatened in 2006. NMFS also determined that the remainder of the proposed species do not warrant listing as endangered or threatened species, and three proposed species (proposed October 2013) were not determinable under the ESA. Only three coral species (*Acropora globicep*s, *A. retusa*, and *Seriatopora aculeata*) are listed under the ESA and occur in the Study Area (Table 3.8-1). New information that supplements existing knowledge on disturbance responses and survivorship of some ESA-listed corals in the genus *Acropora* is detailed in Drury et al. (2017), and reactions of some coral species to thermal stress during a coral restoration project in the Caribbean is documented in (Ladd et al., 2017)). Since the species were listed, there are only a few locations where a federal ESA-listed coral species has been positively identified in the Study Area. Carilli et al. (2018) found ESA-listed corals are present, but rare in waters of <20 m depth around FDM. In April 2015, several colonies of ESA-listed *Acropora globiceps* were encountered during a 40-minute non-systematic survey at Spanish Steps in Outer Apra Harbor (Lybolt, 2015). The colonies were seen in very shallow water less than 3.3 feet (ft.) (1 m) deep. Spanish Steps is just inside the tip of the Orote Peninsula, which is a

dynamic location that is exposed to some effect from the ocean outside the harbor. The area has high coral coverage of commonly seen species from Apra Harbor. A second colony was recorded from the reef crest south of Dadi Beach in September 2016. The single colony was approximately 10–15 inches (25–30 centimeters) across and was observed during a non-systematic survey of the nearshore area at Dadi Beach (Moribe et al., 2016). Even though these observations represent new information on ESA-listed corals, it does not alter the analysis from the 2015 MITT Final EIS/OEIS. Therefore, all other information presented in the 2015 MITT Final EIS/OEIS on corals that occur in the Study Area remains valid.

In 2017, NMFS determined that seven species of giant clam (*Hippopus, H. porcellanus, Tridacna costata, T. derasa, T. gigas, T. squamosa*, and *T. tevoroa*) were candidates that may warrant listing under the ESA (82 Federal Register 28946). A status review is currently being done for these species. Two species, *H. hippopus* and *T. gigas*, have historically been found in the Study Area, but are believed to have been locally extirpated (Meadows, 2016).

Table 3.8-1: Status of Endangered Species Act-Listed Species Within the Study Area

Species Name and Regulatory Status			Presence in Study Area	
Common Name	**Scientific Name**	**Endangered Species Act Status**	**Open Ocean/ Transit Corridor**	**Coastal Ocean**
Staghorn/Stony coral	*Acropora globiceps*	Threatened	No	Yes
Staghorn/Stony coral	*Acropora retusa*	Threatened	No	Yes
Club finger coral	*Seriatopora aculeata*	Threatened	No	Yes
Giant clam	*Hippopus*	Candidate	No	*
Giant clam	*Tridacna gigas*	Candidate	No	*

* May be locally extirpated

3.8.1.4 Taxonomic Groups

The information presented on invertebrate taxonomic groups in the Study Area, as listed in the 2015 MITT Final EIS/OEIS, has not changed and remains valid.

3.8.2 Environmental Consequences

The 2015 MITT Final EIS/OEIS considered training and testing activities proposed to occur in the Study Area that may have the potential to impact marine invertebrates. The stressors applicable to marine invertebrates in the Study Area are the same stressors in the 2015 MITT Final EIS/OEIS and are listed below:

- Acoustic (sonar and other transducers, vessel noise, aircraft noise, weapons noise)
- Explosive (in-air explosions and in-water explosions)
- Energy (in-water electromagnetic devices and high-energy lasers)
- Physical disturbance and strike (vessels and in-water devices, military expended materials, seafloor devices, and personnel disturbance)
- Entanglement (wires and cables, decelerators/parachutes)
- Ingestion (military expended materials – munitions and military expended materials – other than munitions)
- Secondary stressors (impacts on habitat and impacts on prey availability)

This section evaluates how and to what degree potential impacts on marine invertebrates from stressors described in Section 3.0 (General Approach to Analysis) may have changed since the analysis presented in the 2015 MITT Final EIS/OEIS was completed. Tables 2.5-1 and 2.5-2 in Chapter 2 (Description of Proposed Action and Alternatives) list the proposed training and testing activities and include the number of times each activity would be conducted annually and the locations within the Study Area where the activity would typically occur under each alternative. The tables also present the same information for activities described in the 2015 MITT Final EIS/OEIS so that the proposed levels of training and testing under this SEIS/OEIS can be easily compared.

The Navy conducted a review of federal and state regulations and standards relevant to marine invertebrates and reviewed scientific literature published since 2015 for new information on marine invertebrates that could inform the analysis presented in the 2015 MITT Final EIS/OEIS. Since 2006, the Navy, non-Navy scientists, research groups, and universities have conducted scientific monitoring and research in and around ocean areas in the Pacific where the Navy has been and proposes to continue training and testing. The analysis provided in this SEIS/OEIS will be the third time Navy training and testing activities at sea have been comprehensively analyzed in the Study Area. Data collected from the Navy has increased the knowledge of corals in the Study Area. For example, Smith and Marx (2016) conducted a coral reef dive survey on Farallon de Medinilla that used new methods of georeferencing the locations of sighted coral, and documented the existence of a few specimens of two ESA-listed species (*Acropora globiceps* and *Pavona diffluens*), including one species (*Pavona diffluens*) that had not previously been positively identified in the Mariana archipelago. Carilli et al. (2018) found six colonies of possible *Pavona diffluens* (four off the west shoreline, and two off the east shoreline on the northern portion of FDM). The NMFS Final Rule that included the listing of *Pavona diffluens* (79 FR 53851) only included Red Sea/Indian Ocean populations because of taxonomic uncertainty that Pacific populations may be a different species. Because the listing of *Pavona diffluens* only covers colonies outside of the Study Area, this species is not included in the specific analysis of ESA-listed species. Habitat maps were also developed from previous surveys and were refined, confirming that only a small subportion of the nearshore waters were characterized as high-quality coral reef. The analysis presented in this section also considers standard operating procedures, which are discussed in Section 2.3.3 (Standard Operating Procedures) of this Final SEIS/OEIS, and mitigation measures that are described in Chapter 5 (Mitigation). The Navy would implement these measures to avoid or reduce impacts on seafloor resources (including shallow-water coral reefs, live hard bottom, artificial reefs, and shipwrecks) from explosives during applicable activities, as described in Section 5.4.1 (Mitigation Areas for Seafloor Resources).

3.8.2.1 Acoustic Stressors

Little information is available on the potential impacts on marine invertebrates from exposure to sonar and other sound-producing activities. Most studies have focused on a few species (squid or crustaceans) and the consequences of exposures to broadband impulsive air guns typically used for seismic exploration, rather than on sonar or explosions. While the number of training and testing events would change under this SEIS/OEIS, the analysis presented in the 2015 MITT Final EIS/OEIS, Section 3.8.3.1 (Acoustic Stressors), remains applicable. The changes in training and testing activities are not substantial and would not result in an overall change to existing environmental conditions or an increase in the level or intensity of acoustic stressors within the Study Area.

As stated in the 2015 analysis, marine invertebrates are generally not sensitive to most sounds that would result from the proposed activities. New information presented on particle motion detection by

Roberts et al. (2016) found mechanical receptors on some invertebrates may be connected to the central nervous system and can detect some movements or vibrations that are transmitted through substrate. Even though some invertebrates may be able to sense or detect particle motion, they would not be impacted by acoustic sources used during training and testing activities, and a recent literature review on assessing impacts of underwater noise on marine fishes and invertebrates (Hawkins & Popper 2017) does not change this conclusion. Therefore, the analysis presented in the 2015 MITT Final EIS/OEIS, Section 3.8.3.1 (Acoustic Stressors), remains valid and applicable.

3.8.2.1.1 Impacts from Acoustic Stressors Under Alternative 1

Under Alternative 1, there would be an overall decrease in the number of sonar hours used in the Study Area during training and testing activities compared to the number analyzed in the 2015 MITT Final EIS/OEIS (Table 3.0-2 and Figure 2.4-1). Therefore, the analysis in the 2015 MITT Final EIS/OEIS remains valid. Decreases in the number of training and testing events would potentially decrease the level of acoustic stressors in the Study Area. Decreases in sonar hours shown in Table 3.0-2 for activities proposed under Alternative 1 would have no appreciable change on the impact analysis or conclusions for acoustic stressors presented in the 2015 MITT Final EIS/OEIS.

As described in the 2015 MITT Final EIS/OEIS, marine invertebrates throughout the Study Area may be exposed to non-impulsive sounds generated by low-, mid-, and high-frequency sonar and other acoustic sources, vessel noise, and aircraft noise during training and testing activities. Acoustic impacts on marine invertebrates under Alternative 1 would be inconsequential because most marine invertebrates would not be close enough to intense sound sources. Any marine invertebrate capable of sensing sound may alter its behavior and become disoriented due to masking of relevant environmental sounds if exposed to non-impulsive sound, although it is unknown if responses to non-impulsive sounds occur. Continuous noise, such as from vessels, may also contribute to masking of relevant environmental sounds. Because the distance over which most marine invertebrates are expected to detect any sounds is limited and vessels would be in transit, any sound exposures with the potential to cause masking or behavioral responses would last only minutes. Furthermore, invertebrate species have their best sensitivity to sound below 1 kilohertz and would not be capable of detecting the majority of sonars and other acoustic sources used in the Study Area. Therefore, non-impulsive sounds associated with Alternative 1 are not expected to impact the majority of marine invertebrates or cause more than a short-term behavioral disturbance (e.g., change in orientation or swim speeds) to those marine invertebrates capable of detecting nearby sound. No population-level impacts on the survival, growth, recruitment, or reproduction of marine invertebrate populations are expected under Alternative 1.

Pursuant to the ESA, the use of sonar and other transducers associated with training and testing activities, as described under Alternative 1, would have no effect on ESA-listed coral species.

3.8.2.1.2 Impacts from Acoustic Stressors Under Alternative 2 (Preferred Alternative)

Under Alternative 2, the number of sonar hours used during training and testing activities would decrease compared to the numbers analyzed in the 2015 MITT Final EIS/OEIS and increase compared to Alternative 1 of this SEIS/OEIS (Table 3.0-2 and Figure 2.4-1). Under Alternative 2, increases in the number of sonar hours would have no appreciable change on the impact conclusions for acoustic stressors as summarized above under Alternative 1 and as presented in the 2015 MITT Final EIS/OEIS. Therefore, acoustic impacts on marine invertebrates under Alternative 2 would be negligible.

Pursuant to the ESA, the use of sonar and other transducers associated with training and testing activities, as described under Alternative 2, would have no effect on ESA-listed coral species. The Navy is consulting with NMFS as required by Section 7(a)(2) of the ESA.

3.8.2.1.3 Impacts from Acoustic Stressors Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Acoustic stressors as listed above would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer acoustic stressors within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for acoustic impacts on individual invertebrates, but would not measurably improve the status of invertebrate populations or subpopulations.

3.8.2.2 Explosive Stressors

Explosives introduce loud, impulse, broadband sounds into the marine environment. Impulse sources are characterized by rapid pressure rise times and high peak pressures. Explosions produce high-pressure shock waves that could cause injury or physical disturbance due to rapid pressure changes. Impulse sounds are usually brief, but the associated rapid pressure changes can injure or startle marine invertebrates. While the number of training and testing events would change under this SEIS/OEIS, the analysis presented in the 2015 MITT Final EIS/OEIS, Section 3.8.3.1 (Acoustic Stressors), remains applicable. The changes in training and testing activities are not substantial and would not result in an overall change to existing environmental conditions or an increase in the level or intensity of explosive stressors within the Study Area.

As stated above, in the 2015 analysis, and results reported in Roberts et al. (2016) and Edmonds et al. (2016), marine invertebrates are generally not sensitive to most sounds that would result from the proposed activities, but likely have mechanical receptors that may be connected to the central nervous system that can detect some movements or vibrations that are transmitted through substrate. Given that the activities would also be conducted at similar levels as described in the 2015 analysis, there would be no change to the conclusions. Therefore, the analysis presented in the 2015 MITT Final EIS/OEIS, Section 3.8.3.1 (Acoustic Stressors), remains valid.

Although the vast majority of explosions occur at distances greater than 3 nautical miles from shore (where water depths are greater than the depths where shallow-water coral species occur), some explosions may occur close to marine invertebrates that would kill or injure those invertebrates. Explosions near the seafloor and very large explosions in the water column may impact shallow-water corals of any life stage, hard-bottom habitat and associated marine invertebrates, and deep-water corals. Effects could include physical disturbance, fragmentation, or mortality to sessile organisms and pelagic larvae. Energy from an explosion at the surface would dissipate below detectable levels before reaching the seafloor and would not injure or otherwise impact deep-water, benthic marine invertebrates.

3.8.2.2.1 Impacts from Explosive Stressors Under Alternative 1

Under Alternative 1, there would be an overall decrease in the number of explosive ordnance used in the Study Area during training and testing activities compared to the number analyzed in the 2015 MITT Final EIS/OEIS (Table 3.0-7 and Figure 2.4-2). Under Alternative 1, underwater detonations would increase for underwater demolition qualification/certification (Table 2.5-1). However, these activities would continue to occur in the same areas at the Agat Bay site, Piti, and Outer Apra Harbor sites, and would have no appreciable change in the impact analysis or conclusions for explosive stressors as presented in the 2015 MITT Final EIS/OEIS. Decreases in activities proposed under Alternative 1 would have no appreciable change on the impact analysis or conclusions for explosive stressors presented in the 2015 MITT Final EIS/OEIS.

Explosions in the water or near the water surface would injure invertebrates at the surface but would not injure benthic marine invertebrates, including those living in hydrothermal vents, because of the great water depth in areas where most explosive will be used. As described above, explosions at or near the surface would likely kill or injure nearby pelagic marine invertebrates. Effects could include physical disturbance, fragmentation, or mortality.

As described above, the vast majority of explosive detonations during training and testing activities would occur in waters greater than 3 nautical miles from shore, which are not known to support ESA-listed coral species. In addition, energy from an explosion at the surface would dissipate below detectable levels before reaching the seafloor and would not injure or otherwise impact deep-water, benthic marine invertebrates. However, various developmental stages such as eggs, sperm, early embryonic stages, and planula larvae of corals, as well as adults, could be impacted in areas overlapping with other training and testing activities using explosives. Consequences of exposure to an explosive shock wave could include breakage, injury, or mortality. Many corals and hard-bottom invertebrates are sessile, fragile, and particularly vulnerable. Because exposures to explosive shock waves are brief, limited in number, and spread over a large area, no long-term impacts are expected. Explosives may impact individual marine invertebrates and groups of marine invertebrates, but they are unlikely to impact populations or subpopulations. Therefore, impacts of explosives on marine invertebrates under Alternative 1 would be negligible.

As discussed in Section 5.4.1 (Mitigation Areas for Seafloor Resources), the Navy will implement mitigation to avoid or reduce impacts from explosives on seafloor resources in mitigation areas throughout the Study Area. For example, the Navy will not conduct explosive mine countermeasure and neutralization activities within a specified distance of shallow-water coral reefs, live hard bottom, artificial reefs, and shipwrecks. The mitigation will consequently also help avoid or reduce potential impacts on invertebrates that inhabit these areas. There is also procedural mitigation that affects "jellyfish aggregations," specifically for explosive torpedoes and sinking exercises (see Section 5.3.3, Explosive Stressors). Additionally, the Navy will require Lookouts to observe the water's surface before and during sinking exercises and the use of explosive torpedoes to avoid or reduce jellyfish aggregations.

Pursuant to the ESA, the use of explosives associated with training and testing activities, as described under Alternative 1, may affect ESA-listed coral species.

3.8.2.2.2 Impacts from Explosive Stressors Under Alternative 2 (Preferred Alternative)

Under Alternative 2, the number of explosives used during training and testing activities would decrease compared to the numbers analyzed in the 2015 MITT Final EIS/OEIS and increase compared to Alternative 1 (Table 3.0-7 and Figure 2.4-2). Under Alternative 2, increases in the number of underwater

explosives would have no appreciable change on the impact conclusions for explosive stressors as summarized above under Alternative 1 and as presented in the 2015 MITT Final EIS/OEIS.

Therefore, impacts on marine invertebrates under Alternative 2 from explosives would be negligible.

Pursuant to the ESA, the use of explosives associated with training and testing activities, as described under Alternative 2, may affect ESA-listed coral species. The Navy is consulting with NMFS as required by Section 7(a)(2) of the ESA.

3.8.2.2.3 Impacts from Explosive Stressors Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Explosive stressors as listed above would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer explosive stressors within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for explosive impacts on individual invertebrates, but would not measurably improve the status of invertebrate populations or subpopulations.

3.8.2.3 Energy Stressors

The energy stressors that may impact marine invertebrates include in-water electromagnetic devices and high energy lasers. The in-water electromagnetic devices stressor remains the same as analyzed in the 2015 MITT Final EIS/OEIS; high-energy lasers is a new stressor analyzed in this SEIS/OEIS. While the number of training and testing events would change under this SEIS/OEIS, the analysis presented in the 2015 MITT Final EIS/OEIS for in-water electromagnetic devices remains valid and an analysis of potential impacts from high-energy laser use is presented below.

As discussed in Section 3.0.5.3.1.2 (High-Energy Lasers), high-energy lasers are designed to disable surface targets, rendering them immobile. The primary concern is the potential for an invertebrate to be struck with the laser beam at or near the water's surface, where extended exposure could result in injury or death.

Little information exists about marine invertebrates' susceptibility to electromagnetic fields. Most corals are thought to use water temperature, day length, lunar cycles, and tidal fluctuations as cues for spawning. Magnetic fields are not known to influence coral spawning or larval settlement. However, existing information suggests sensitivity to electric and magnetic fields in at least three marine invertebrate phyla: Mollusca, Arthropoda, and Echinodermata (Lohmann et al., 1995; Lohmann & Lohmann, 2006; Normandeau et al., 2011).

High-energy lasers were not proposed for use in the 2015 MITT Final EIS/OEIS. As discussed in Section 3.0.4.3.2.2 (High-Energy Lasers), high-energy laser weapons testing involves the use of directed energy as a weapon against small surface vessels and airborne targets. These weapons systems are deployed from a surface ship to create small but critical failures in potential targets and used at short ranges from the target.

Marine invertebrates could be exposed to a laser only if the beam missed the target. Should the laser strike the sea surface, individual invertebrates at or near the surface, such as jellyfish, floating eggs, and

larvae could potentially be exposed. The potential for exposure to a high-energy laser beam decreases rapidly as water depth increases and varies with time of day, as many zooplankton species migrate away from the surface during the day. Most marine invertebrates, including those that live in hydrothermal vents, are not susceptible to laser exposure because they occur beneath the sea surface.

3.8.2.3.1 Impacts from In-Water Electromagnetic Devices Under Alternative 1

Under Alternative 1, the number of proposed training and testing activities involving the use of in-water electromagnetic devices would decrease in comparison to the 2015 MITT Final EIS/OEIS (Table 3.0-9). The activities would occur in the same locations and in a similar manner as were analyzed previously.

Therefore, impacts on marine invertebrates under Alternative 1 from in-water electromagnetic devices would be negligible.

Pursuant to the ESA, the use of in-water electromagnetic devices associated with training and testing activities, as described under Alternative 1, would have no effect on ESA-listed coral species.

3.8.2.3.2 Impacts from In-Water Electromagnetic Devices Under Alternative 2 (Preferred Alternative)

Under Alternative 2, the number of proposed training and testing activities involving the use of in-water electromagnetic devices would decrease in comparison to the 2015 MITT Final EIS/OEIS (Table 3.0-9). The activities would occur in the same locations and in a similar manner as were analyzed previously and above for Alternative 1.

Therefore, impacts on marine invertebrates under Alternative 2 from in-water electromagnetic devices would be negligible.

Pursuant to the ESA, the use of in-water electromagnetic devices associated with training and testing activities, as described under Alternative 2, would have no effect on ESA-listed coral species. The Navy is consulting with NMFS as required by Section 7(a)(2) of the ESA.

3.8.2.3.3 Impacts from In-Water Electromagnetic Devices Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Energy stressors as listed above would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer in-water electromagnetic stressors within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for energy impacts on individual invertebrates, but would not measurably improve the status of invertebrate populations or subpopulations.

3.8.2.3.4 Impacts from High-Energy Lasers Under Alternative 1

No high-energy lasers are proposed for training activities under Alternative 1. Under Alternative 1, the number of proposed testing events involving the use of high-energy lasers would be 54 (Table 3.0-10); this is a new substressor that was not analyzed in the 2015 MITT Final EIS/OEIS.

The primary concern for high-energy weapons testing is the potential for a marine invertebrate to be struck by a high-energy laser beam at or near the water's surface, which could result in injury or death, resulting from traumatic burns from the beam. Invertebrates that do not occur at or near the sea

surface would not be exposed due to the attenuation of laser energy with depth. Surface invertebrates such as squid, jellyfish, and zooplankton (which may include invertebrate larvae) exposed to high-energy lasers could be injured or killed, but the probability is low based on the relatively low number of events, very localized potential impact area of the laser beam, and the temporary duration of potential impact (seconds). Activities involving high-energy lasers are not expected to yield any behavioral changes or lasting effects on the survival, growth, recruitment, or reproduction of invertebrate species at the population level because of the relatively small number of individuals that could be impacted. The impact of high-energy lasers on marine invertebrates, including those that live in hydrothermal vents, would be inconsequential because (1) it is highly unlikely that a high-energy laser would miss its target, (2) it is highly unlikely that the laser would miss in such a way that the laser beam would strike a marine invertebrate, and (3) it is highly unlikely that the marine invertebrate would be at or near the surface, just as two equally unlikely events take place.

Pursuant to the ESA, the use of high-energy lasers associated with testing activities, as described under Alternative 1, would have no effect on ESA-listed coral species.

3.8.2.3.5 Impacts from High-Energy Lasers Under Alternative 2 (Preferred Alternative)

As shown in Table 3.0-10, 60 testing events involving the use of high-energy lasers are proposed under Alternative 2, which is a slight increase from the number proposed under Alternative 1. Therefore, the impacts would be the same as described under Alternative 1.

Pursuant to the ESA, the use of high-energy lasers associated with testing activities, as described under Alternative 2, would have no effect on ESA-listed coral species. The Navy is consulting with NMFS as required by Section 7(a)(2) of the ESA.

3.8.2.3.6 Impacts from High-Energy Lasers Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Energy stressors as listed above would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer high-energy laser stressors within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for energy impacts on individual invertebrates, but would not measurably improve the status of invertebrate populations or subpopulations.

3.8.2.4 Physical Disturbance and Strike Stressors

The physical disturbance and strike stressors that may impact marine invertebrates include (1) vessels and in-water devices, (2) military expended materials, (3) seafloor devices, and (4) personnel disturbance. While the number of training and testing events would change under this SEIS/OEIS, the analysis presented in the 2015 MITT Final EIS/OEIS, Section 3.8.3.3 (Physical Disturbance and Strike Stressors) remains valid. The changes in training and testing activities are not substantial and would not result in an overall change to existing environmental conditions or an increase in the level or intensity of physical disturbance and strike stressors within the Study Area.

Most marine invertebrate populations, including those that live in hydrothermal vents, extend across wide areas containing hundreds or thousands of discrete patches of suitable habitat. Sessile (attached to the seafloor or other surface) invertebrate populations may be maintained by complex currents that carry adults and young from place to place. Such widespread populations are difficult to evaluate in terms of Navy training and testing activities that occur intermittently and in relatively small patches in the Study Area. Even invertebrate populations that are somewhat restricted in range, such as coral reefs, cover enormous areas (see Section 3.3, Marine Habitats, for quantitative assessments). In this context, a physical strike or disturbance would impact individual organisms directly or indirectly.

As stated in the 2015 MITT Final EIS/OEIS, activities involving vessels and in-water devices are not intended to contact the seafloor. This would include amphibious and expeditionary events such as Amphibious Assaults, Amphibious Raids, Personnel Insertion/Extraction, and Underwater Surveys, which are proposed to continue in this SEIS/OEIS. These activities could occur at beaches at Babui, Chulu, and Dankulo on Tinian and could also occur at Dry Dock Island in Apra Harbor at Dadi Beach on Guam. During these activities, combat swimmers and other military personnel may be required to walk through nearshore areas. For example, as the boat approaches a beach, military personnel may be required to exit the boat, stand up, and walk through the shallow water habitats, which could disturb or injure some marine invertebrates. Benthic invertebrates of the reef crest or flat, such as crabs, clams, and polychaete worms, within the disturbed area could be displaced, injured, or killed during amphibious operations. As is current practice, coral and other hard bottom habitats would continue to be avoided to the greatest extent practical under the Proposed Action (see Section 2.3.3, Standard Operating Procedures and Chapter 5, Mitigation). However, combat swimmers and Marines may be required to walk through nearshore areas during these activities. For example, as the boat approaches a beach, Marines may be required to exit the boat, stand up, and walk through the shallow water habitats.

As discussed in Section 5.4.1 (Mitigation Areas for Seafloor Resources), the Navy will implement mitigation to avoid or reduce impacts from precision anchoring and military expended materials on seafloor resources in mitigation areas throughout the Study Area. For example, the Navy will not conduct explosive mine countermeasure and neutralization activities within a specified distance of shallow-water coral reefs, live hard bottom, artificial reefs, and shipwrecks (except at designated nearshore training areas, where these resources will be avoided to the maximum extent practicable). The mitigation will consequently also help avoid or reduce potential impacts on invertebrates that inhabit these areas.

3.8.2.4.1 Impacts from Physical Disturbance and Strike Stressors Under Alternative 1

Under Alternative 1, the combined number of proposed training and testing activities involving vessels and in-water devices (Table 3.0-12 and Table 3.0-13) would decrease slightly from those presented in the 2015 MITT Final EIS/OEIS. Military expended materials and munitions (Tables 3.0-14 through 3.0-17) combined would increase, and seafloor devices (Table 3.0-19) would decrease slightly from the number in the 2015 MITT Final EIS/OEIS, as well as the overall reduction of the footprint of expended materials. Increases in some physical disturbance and strike stressors, such as military expended materials, could increase the level of impact on some marine invertebrates, including those that live in hydrothermal vents. However, these changes do not appreciably change the analysis or impact conclusions presented in the 2015 MITT Final EIS/OEIS because the impact analysis was based on the probability of an impact on a resource.

As stated in the 2015 MITT Final EIS/OEIS, the impact of physical disturbance and strike stressors on marine invertebrates is likely to cause injury or mortality to individuals, such as corals on nearshore

reefs, but impacts on populations, including those that live in hydrothermal vents, would be negligible because (1) the area exposed to the stressor is extremely small (localized) relative to most marine invertebrates' ranges, and (2) the activities are dispersed such that few individuals could conceivably be exposed to more than one event. Activities involving vessel and in-water devices, military expended material, seafloor devices, and personnel disturbance are not expected to yield any behavioral changes or lasting effects on the survival, growth, recruitment, or reproduction of invertebrate species at the population level. However, the combined consequences of all physical disturbance and strike stressors could degrade habitat quality at some locations. As stated above, combat swimmers and Marines may be required to walk through nearshore areas and reefs during these activities, potentially causing damage to coral species. As stated in the 2015 MITT Final EIS/OEIS and above, these activities could cause injury or mortality to individuals, but impacts on marine invertebrate populations, including ESA-listed corals, are unlikely.

Therefore, under Alternative 1, impacts on marine invertebrates from the use of vessels and in-water devices, military expended materials, and seafloor devices would be negligible.

Pursuant to the ESA, the use of vessels and in-water devices, military expended materials, and seafloor devices during training and testing activities, as described under Alternative 1, may affect ESA-listed coral species.

3.8.2.4.2 Impacts from Physical Disturbance and Strike Stressors Under Alternative 2 (Preferred Alternative)

Under Alternative 2, the combined number of proposed training and testing activities involving vessels and in-water devices would decrease slightly from those presented in the 2015 MITT Final EIS/OEIS (Table 3.0-12 and Table 3.0-13). Military expended materials (Tables 3.0-14 through 3.0-17) combined would increase, and seafloor devices (Table 3.0-19) would decrease slightly from the numbers in the 2015 MITT Final EIS/OEIS. Increases in some physical disturbance and strike stressors such as military expended materials could increase the impact risk on marine invertebrates, but do not appreciably change the analysis or impact conclusions presented in the 2015 MITT Final EIS/OEIS. Impacts on marine invertebrates would be inconsequential for the same reasons detailed above and there would be no appreciable change in the impact conclusions for physical disturbance and strike stressors, as presented in the 2015 MITT Final EIS/OEIS and summarized above under Alternative 1.

Therefore, under Alternative 2, impacts on marine invertebrates from the use of vessels and in-water devices, military expended materials, and seafloor devices would be negligible.

Pursuant to the ESA, the use of vessels and in-water devices, military expended materials, and seafloor devices during training and testing activities, as described under Alternative 2, may affect ESA-listed coral species. The Navy is consulting with NMFS as required by Section 7(a)(2) of the ESA.

3.8.2.4.3 Impacts from Physical Disturbance and Strike Stressors Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Physical disturbance and strike stressors as listed above would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer physical disturbance and strike stressors within the marine environment where Navy activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the

potential for physical disturbance and strike impacts on individual invertebrates, but would not measurably improve the status of invertebrate populations or subpopulations.

3.8.2.5 Entanglement Stressors

Entanglement stressors that may impact marine invertebrates include (1) fiber optic cables and guidance wires, and (2) decelerators/parachutes. While the number of training and testing events would change under this supplement, the analysis presented in the 2015 MITT Final EIS/OEIS, Section 3.8.3.4 (Entanglement Stressors) remains valid.

3.8.2.5.1 Impacts from Entanglement Stressors Under Alternative 1

Under Alternative 1, the number of fiber optic cables (Table 3.0-22), guidance wires (Table 3.0-22), and decelerators/parachutes (Table 3.0-24) that would be expended during training and testing activities would decrease compared to the number of activities proposed in the 2015 MITT Final EIS/OEIS. Decreases in the number of training and testing events would potentially decrease the level of entanglement stressors in the Study Area.

As stated in the 2015 MITT Final EIS/OEIS, the impact of fiber optic cables, guidance wires, and decelerators/parachutes on marine invertebrates, including those that live in hydrothermal vents, is not likely to cause injury or mortality to individuals, and impacts would be negligible because (1) the area exposed to the stressor is extremely small (localized) relative to most marine invertebrates' ranges, (2) the activities are dispersed such that few individuals could conceivably be exposed to more than one activity, and (3) marine invertebrates are not particularly susceptible to entanglement stressors. Activities involving cables, guidance wires, and decelerators/parachutes are not expected to yield any behavioral changes or lasting impacts on the survival, growth, recruitment, or reproduction of invertebrate species at individual or population levels.

Therefore, impacts on marine invertebrates from entanglement stressors such as wires and cables and decelerators/parachutes under Alternative 1 would be negligible.

Pursuant to the ESA, the use of fiber optic cables and guidance wires, and decelerators/parachutes *during training and testing activities, as described under Alternative 1, may affect ESA-listed coral species.*

3.8.2.5.2 Impacts from Entanglement Stressors Under Alternative 2 (Preferred Alternative)

Under Alternative 2, the number of fiber optic cables (Table 3.0-22) decrease, guidance wires (Table 3.0-22) increase, and decelerators/parachutes (Table 3.0-24) decrease compared to the number of activities proposed in the 2015 MITT Final EIS/OEIS and would increase or stay the same compared to Alternative 1. However, as stated above for Alternative 1, training and testing activities involving fiber optic cables, guidance wires, and decelerators/parachutes are not expected to yield any behavioral changes or lasting impacts on the survival, growth, recruitment, or reproduction of invertebrate species at individual or population levels for the same reasons detailed above for Alternative 1.

Therefore, impacts on marine invertebrates from entanglement stressors such as wires and cables and decelerators/parachutes under Alternative 2 would be negligible.

Pursuant to the ESA, the use of fiber optic cables and guidance wires, and decelerators/parachutes *during training and testing activities, as described under Alternative 2, may affect ESA-listed coral species. The Navy is consulting with NMFS as required by Section 7(a)(2) of the ESA.*

3.8.2.5.3 Impacts from Entanglement Stressors Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Entanglement stressors as listed above would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer entanglement stressors within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for entanglement impacts on individual invertebrates, but would not measurably improve the status of invertebrate populations or subpopulations.

3.8.2.6 Ingestion Stressors

Types of materials that could become ingestion stressors during training and testing activities in the Study Area include non-explosive practice munitions (small- and medium-caliber), fragments from explosives, fragments from targets, chaff, flare casings (including plastic end caps and pistons), and decelerators/parachutes. While the number of training and testing events would change under this SEIS/OEIS, the analysis presented in the 2015 MITT Final EIS/OEIS, Section 3.8.3.5 (Ingestion Stressors) remains valid.

Expended materials could be ingested by marine invertebrates at the surface, in the water column, or on the seafloor, depending on the size and buoyancy of the expended object and the feeding behavior of the animal. Floating material is more likely to be eaten by animals that feed at or near the water surface, while materials that sink to the seafloor present a higher risk to both filter-feeding sessile (i.e., corals) and bottom-feeding animals (seastars and sea cucumbers). Marine invertebrates are universally present in the water and the seafloor, with many individuals being smaller than a few millimeters (e.g., zooplankton, most roundworms, and most arthropods). Most military expended materials and fragments of military expended materials are too large to be ingested by marine invertebrates. The potential for marine invertebrates to encounter fragments of ingestible size increases as the military expended materials degrade into smaller fragments.

3.8.2.6.1 Impacts from Ingestion Stressors Under Alternative 1

Under Alternative 1, the combined number of ingestion stressors would increase compared to the number in the 2015 MITT Final EIS/OEIS (see Tables 3.0-14 through 3.0-17, Table 3.0-25, and Table 3.0-26). However, increases in the number of ingestion stressors do not appreciably change the impact analysis or conclusions presented in the 2015 MITT Final EIS/OEIS.

As stated in the 2015 MITT Final EIS/OEIS, most military expended materials and fragments of military expended materials are too large to be ingested by marine invertebrates, including those that live in hydrothermal vents. The potential for marine invertebrates to encounter fragments of ingestible size increases as the military expended materials degrade into smaller fragments. The increase in military expended materials, primarily from small-caliber projectiles, would not represent an ingestion risk for marine invertebrates. Only a small fraction of military expended materials would be of ingestible size, or become ingestible after degradation; while those may impact individual marine invertebrates, such as ESA-listed corals, they are unlikely to impact populations. Therefore, impacts on marine invertebrates from ingestion of military expended materials under Alternative 1 would be negligible.

Pursuant to the ESA, the use of military expended materials of ingestible size during training and testing activities, as described under Alternative 1, may affect ESA-listed coral species.

3.8.2.6.2 Impacts from Ingestion Stressors Under Alternative 2 (Preferred Alternative)

Under Alternative 2, the combined number of ingestion stressors would increase compared to the number in the 2015 MITT Final EIS/OEIS and as compared to Alternative 1 (see Tables 3.0-14 through 3.0-17, Table 3.0-25, and Table 3.0-26). However, these increases do not appreciably change the impact analysis or conclusions presented in the 2015 MITT Final EIS/OEIS and those summarized above under Alternative 1.

Therefore, impacts on marine invertebrates from ingestion of military expended materials under Alternative 2 would be negligible.

Pursuant to the ESA, the use of military expended materials of ingestible size during training and testing activities, as described under Alternative 2, may affect ESA-listed coral species. The Navy is consulting with NMFS as required by Section 7(a)(2) of the ESA.

3.8.2.6.3 Impacts from Ingestion Stressors Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Ingestion stressors as listed above would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer ingestion stressors within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for ingestion impacts on individual invertebrates, but would not measurably improve the status of invertebrate populations or subpopulations.

3.8.2.7 Secondary Stressors

Potential impacts on marine invertebrates exposed to stressors could occur indirectly through sediments and water quality. Stressors from Navy training and testing activities could pose secondary or indirect impacts on marine invertebrates via habitat, sediment, or water quality. Components of these stressors that could pose indirect impacts include (1) explosives and byproducts; (2) metals; (3) chemicals; and (4) other materials such as targets, chaff, and plastics.

While the number of training and testing events would change under this SEIS/OEIS, the analysis presented in the 2015 MITT Final EIS/OEIS, Section 3.8.3.6 (Secondary Stressors) remains valid. As stated in the 2015 MITT Final EIS/OEIS, indirect impacts of explosives and unexploded ordnance on marine invertebrates via water are likely to be negligible and not detectable for two reasons. First, most explosives and explosive degradation products have very low solubility in sea water. This means that dissolution occurs extremely slowly, and harmful concentrations of explosives and degradation are not likely to accumulate except within confined spaces. Second, a low concentration of byproducts, slowly delivered into the water column, is readily diluted to non-harmful concentrations. Filter feeders in the immediate vicinity of degrading explosives may be more susceptible to bioaccumulation of chemical byproducts. While marine invertebrates may be adversely impacted by the indirect effects of degrading explosives via water (Rosen & Lotufo, 2007; 2010), this is extremely unlikely in realistic scenarios.

Impacts on marine invertebrates, including zooplankton, eggs, and larvae, are likely within a very small radius of the ordnance (1–6 ft. [0.3–1.8 m]). These impacts may continue as the ordnance degrades over months to decades. Because most ordnance is deployed as projectiles, multiple unexploded or low-order detonations would accumulate on spatial scales of 1 to 6 ft. (0.3 to 1.8 m.); therefore, potential impacts are likely to remain local and widely separated. Given these conditions, the possibility of population-level impacts on marine invertebrates is negligible. However, if the sites of the depositions are the same over time, this could alter the benthic composition, affect bioaccumulation, and impact local invertebrate communities.

Erosion as a result of training activities at FDM may contribute to deposition of soils into the nearshore areas of FDM, causing increased turbidity. However, cliff face vertical targets used as part of Naval surface fire support training have been moved to reduce erosion and potential impacts on the cliff face, as well as biological resources. Turbidity can impact corals and invertebrate communities on hard-bottom areas by reducing the amount of light that reaches these organisms and by clogging siphons for filter-feeding organisms. Reef-building corals are sensitive to water clarity because they host symbiotic algae that require sunlight to live. Encrusting organisms residing on hard bottom can be impacted by persistent silting from increased turbidity. However, the impacts of explosive byproducts on sediment and water quality would be indirect, short term, local, and negative. Explosive ordnance could loosen soil on FDM, and runoff from surface drainage areas containing soil and explosive byproducts could subsequently enter nearshore waters. Impacts on marine invertebrates from erosion or sedimentation could occur.

As stated in the 2015 MITT Final EIS/OEIS, concentrations of metals in water are extremely unlikely to be high enough to cause injury or mortality to marine invertebrates; therefore, indirect impacts of metals via water are likely to be negligible and not detectable. Given these conditions, the possibility of population-level impacts on marine invertebrates is likely to be negligible and not detectable. In addition, concentrations of chemicals in sediment and water are not likely to cause injury or mortality to marine invertebrates; therefore, indirect impacts of chemicals via sediment and water are likely to be negligible and not detectable. Population-level impacts on marine invertebrates would be negligible and not detectable.

In addition, as stated in the 2015 MITT Final EIS/OEIS, plastics could impact marine invertebrates via sediment. Harmful chemicals in plastics interfere with metabolic and endocrine processes in many plants and animals (Derraik, 2002). Potentially harmful chemicals in plastics are not readily adsorbed to marine sediments; instead, marine invertebrates are most at risk via ingestion or bioaccumulation. Because plastics retain many of their chemical properties as they are physically degraded into microplastic particles (Singh & Sharma, 2008), the exposure risks to marine invertebrates are dispersed over time. Marine invertebrates could be indirectly impacted by chemicals from plastics but, absent bioaccumulation, these impacts would be limited to direct contact with the material because relatively few military expended materials contain plastics. Therefore, population-level impacts on marine invertebrates attributable to Navy-expended materials are likely to be negligible and not detectable.

3.8.3 Public Comments

The public raised a number of issues during the scoping period in regard to marine invertebrates. The issues are summarized in the list below. Comments received from the public during the Draft SEIS/OEIS commenting period related to marine invertebrates are addressed in Appendix K (Public Comment Responses).

- **Sonar disrupting larval recruitment –** As described in the 2015 MITT Final EIS/OEIS, corals throughout the Study Area may be exposed to non-impulse sounds generated by sonar and other transducers, vessels, and aircraft during training and testing activities. However, the vast majority of underwater acoustic sources would not be used in the shallow waters (less than 100 ft. [30 m.]) where the majority of coral species are known to exist. Sound from training and testing activities is intermittent or transient, or both, and would not occur close enough to reefs to interfere with larval perception of reef noise. The Navy also looked at impacts on the individual polyp or medusae from the use of sonar in relation to the overall number, or population, of coral medusae or polyps. In addition, as described above in Section 3.8.1.1 (Sound Sensing and Production), invertebrate species detect sounds through particle motion, which diminishes rapidly from the sound source. Most activities using sonar or other transducers would be conducted in deep-water, offshore areas of the Study Area and would not affect invertebrates. Furthermore, invertebrate species have their best hearing sensitivity below 1 kHz and would not be capable of detecting the majority of sonars and other transducers used in the Study Area.
- **Impacts from precision anchoring activities –** As described in Section 3.7.3.2.3 (Impacts from Seafloor Devices) of the 2015 MITT Final EIS/OEIS, precision anchoring would typically occur within predetermined shallow water anchorage locations near ports where the seafloor consists of unconsolidated sediments and lacks marine vegetation. These areas do not contain coral reefs. Additional mitigation measures for shallow water coral reefs used to avoid or reduce impacts from precision anchoring are presented in Chapter 5 (Mitigation).
- **Persistence of chemicals in ordnance when debris becomes encased in coral** – As described in Section 3.8.3.3.2.1 (Military Expended Materials that are Ordnance) of the 2015 MITT Final EIS/OEIS, the physical and chemical properties of the surrounding water from an ordnance strike would be temporarily altered (e.g., slight heating or cooling and increased oxygen concentrations due to turbulent mixing with the atmosphere), but there would be no lasting change resulting in long-term impacts on marine invertebrates. In addition, Section 3.8.3.6 (Secondary Impacts) in the 2015 MITT Final EIS/OEIS determined that the impacts on sedentary invertebrate beds and reefs from the use of metal, chemical, and other material byproducts, and secondary physical disturbances during training and testing activities would be minimal and short term within the Study Area.
- **Secondary impacts on ESA species, including coral reefs from training activities on FDM –** The 2015 MITT Final EIS/OEIS analyzed potential impacts on marine resources, including ESA-listed coral species, using the best available data. Similarly, the Navy conducted an extensive review of recent literature, including government technical documents and reports, and online scientific journal databases to add any new information to this document. This information supports the conclusions from the 2015 MITT Final EIS/OEIS that secondary impacts on coral reefs from explosives and explosive byproducts could occur, while impacts on marine invertebrates from erosion or sedimentation are not anticipated. In addition, indirect impacts from metals and other chemicals in the marine environment are likely to be negligible and not detectable.
- **Direct impacts on coral reefs, coral spawning periods, and other invertebrates from sedimentation/erosion around FDM –** As detailed in Section 3.1 (Sediments and Water Quality), recent multi-year dive studies were conducted by Smith and Marx (2016) at FDM. These surveys found that coral fauna at FDM are healthy and robust and the nearshore physical environment

and basic habitat types at FDM remained unchanged over the 13 years (1999–2012). These conclusions are based on (1) a limited amount of physical damage, (2) very low levels of partial mortality and disease (less than 1 percent of all species observed), (3) absence of excessive mucus production, (4) good coral recruitment, (5) complete recovery by 2012 of the 2007 bleaching event, and (6) a limited number of macrobioeroders and an absence of invasive crown of thorns starfish (*Acanthaster planci*). These factors suggest that sedimentation that may result from military use of FDM is not sufficient as to adversely impact water quality and coral communities. A recent coral reef survey by Carilli et al. (2018) at FDM verified Endangered Species Act (ESA)-listed corals, quantified coral reef health, and compiled observations of ordnance impacts. The survey results indicated that ESA-listed corals are present, but rare in waters of <20 meters depth around FDM. Additionally, 77.3 percent of corals observed exhibited some form of bleaching, likely caused by regionally anomalous warm sea surface temperatures. Carilli et al. (2018) also found little evidence of adverse impacts on coral from Navy training at FDM, including from the use of high-explosive bombs. In addition, they found that scleractinian coral growth occurred on a substantial percentage of ordnance items expended.

- **Direct and cumulative impacts from military expended materials as marine debris –** The 2015 MITT Final EIS/OEIS and this SEIS/OEIS analyzed potential direct and cumulative impacts of military expended materials on marine invertebrates through physical disturbance and strike, entanglement, and ingestion. The majority of these materials are expended in open ocean areas where impacts on biological communities, such as coral reefs, would be minimized.

3.9 Fishes

3.9.1 Affected Environment

The purpose of this section is to supplement the analysis of impacts on fishes presented in the 2015 Mariana Islands Training and Testing (MITT) Final Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS) with new information relevant to proposed changes in training and testing activities conducted at sea and on Farallon de Medinilla. New information made available since the publication of the 2015 MITT Final EIS/OEIS is included below to better understand potential stressors and impacts on fishes resulting from training and testing activities. Comments received from the public during scoping related to fishes are addressed in Section 3.9.3 (Public Comments). Comments received from the public during the Draft Supplemental EIS (SEIS)/OEIS commenting period related to fishes are addressed in Appendix K (Public Comment Responses).

3.9.1.1 Hearing and Vocalization

A summary of fish hearing and vocalizations is described in the 2015 MITT Final EIS/OEIS. Due to the availability of new literature, including revised sound exposure criteria, the information provided below will supplement the 2015 MITT Final EIS/OEIS for fishes.

All fishes have two sensory systems that can detect sound in the water: the inner ear, which functions similarly to the inner ear in other vertebrates, and the lateral line, which consists of a series of receptors along the body of a fish (Popper, 2008). The lateral line system is sensitive to external particle motion arising from sources within a few body lengths of an animal. The lateral line detects particle motion at low frequencies from below 1 hertz (Hz) up to at least 400 Hz (Coombs & Montgomery, 1999; Hastings & Popper, 2005; Higgs & Radford, 2013; Webb et al., 2008). Generally, the inner ears of fish contain three types of dense otoliths (i.e., small calcareous bodies) that sit atop many delicate mechanoelectric hair cells within the inner ear of fishes, similar to the hair cells found in the mammalian ear. Underwater sound waves pass through the fish's body and vibrate the otoliths. This causes a relative motion between the dense otoliths and the surrounding tissues, causing a deflection of the hair cells, which is sensed by the nervous system.

Although a propagating sound wave contains pressure and particle motion components, particle motion is most significant at low frequencies (up to at least 400 Hz) and is most detectible at high sound pressures or very close to a sound source. The inner ears of fishes are directly sensitive to acoustic particle motion rather than acoustic pressure (acoustic particle motion and acoustic pressure are discussed in Appendix H, Acoustic and Explosive Concepts). Historically, studies that have investigated hearing in, and effects to, fishes have been carried out with sound pressure metrics. Although particle motion may be the more relevant exposure metric for many fish species, there is little data available that actually measures it due to a lack in standard measurement methodology and experience with particle motion detectors (Hawkins et al., 2015; Martin et al., 2016). In these instances, particle motion can be estimated from pressure measurements (Nedelec et al., 2016a).

Some fishes possess additional morphological adaptations or specializations that can enhance their sensitivity to sound pressure, such as a gas-filled swim bladder (Astrup, 1999; Popper & Fay, 2010). The swim bladder can enhance sound detection by converting acoustic pressure into localized particle motion, which may then be detected by the inner ear (Radford et al., 2012). Fishes with a swim bladder generally have greater hearing sensitivity and can detect higher frequencies than fishes without a swim bladder (Popper & Fay, 2010; Popper et al., 2014). In addition, structures such as gas-filled bubbles near

the ear or swim bladder, or even connections between the swim bladder and the inner ear, also increase sensitivity and allow for high-frequency hearing capabilities and better sound pressure detection.

Although many researchers have investigated hearing and vocalizations in fish species (Ladich & Fay, 2013; Popper et al., 2014), hearing capability data only exist for just over 100 of the currently known 34,000 marine and freshwater fish species (Eschmeyer & Fong, 2017). Therefore, fish hearing groups are defined by species that possess a similar continuum of anatomical features, which result in varying degrees of hearing sensitivity (Popper & Fay, 2010). Categories and descriptions of hearing sensitivities are further defined in this document (modified from Popper et al., 2014) as the following:

- Fishes without a swim bladder—hearing capabilities are limited to particle motion detection at frequencies well below 2 kilohertz (kHz).
- Fishes with a swim bladder not involved in hearing—species lack notable anatomical specializations and primarily detect particle motion at frequencies below 2 kHz.
- Fishes with a swim bladder involved in hearing—species can detect frequencies below 2 kHz and possess anatomical specializations to enhance hearing, and are capable of sound pressure detection up to a few kHz.
- Fishes with a swim bladder and high-frequency hearing—species can detect frequencies below 2 kHz and possess anatomical specializations, and are capable of sound pressure detection at frequencies up to 10 kHz to over 100 kHz.

Data suggest that most species of marine fish either lack a swim bladder (e.g., sharks and flatfishes) or have a swim bladder not involved in hearing and can only detect sounds below 1 kHz. Some marine fishes (Clupeiformes) with a swim bladder involved in hearing are able to detect sounds to about 4 kHz (Colleye et al., 2016; Mann et al., 2001; Mann et al., 1997). One subfamily of clupeids (i.e., Alosinae) can detect high- and very high-frequency sounds (i.e., frequencies from 10 to 100 kHz, and frequencies above 100 kHz, respectively), although auditory thresholds at these higher frequencies are elevated and the range of best hearing is still in the low-frequency range (below 1 kHz) similar to other fishes. Mann et al. (1997; 1998) theorize that this subfamily may have evolved the ability to hear relatively high sound levels at these higher frequencies in order to detect echolocations of nearby foraging dolphins. For fishes that have not had their hearing tested, such as deep sea fishes, the suspected hearing capabilities are based on the structure of the ear, the relationship between the ear and the swim bladder, and other potential adaptations such as the presence of highly developed areas of the brain related to inner ear and lateral line functions (Buran et al., 2005; Deng et al., 2011, 2013). It is believed that most fishes have their best hearing sensitivity from 100 to 400 Hz (Popper, 2003).

Endangered Species Act (ESA)-listed species with the potential to occur within the MITT Study Area hammerhead shark (*Sphyrna lewini*), the oceanic whitetip shark (*Carcharhinus longimanus*), and the giant manta ray (*Manta birostris*). As discussed above, most marine fishes investigated to date lack hearing capabilities greater than 1,000 Hz. Rays and sharks are cartilaginous fishes (i.e., elasmobranchs) lacking a swim bladder. Available data suggest these species can detect sounds from 20 to 1,000 Hz, with best sensitivity at lower ranges (Casper et al., 2003; Casper & Mann, 2006; Casper & Mann, 2009; Myrberg, 2001).

Some fishes are known to produce sound. Bony fishes can produce sounds in a number of ways and use them for a number of behavioral functions (Ladich, 2008, 2014). Over 30 families of fishes are known to use vocalizations in aggressive interactions, and over 20 families are known to use vocalizations in mating (Ladich, 2008). Sounds generated by fishes as a means of communication are generally below

500 Hz (Slabbekoorn et al., 2010). The air in the swim bladder is vibrated by the sound producing structures (often muscles that are integral to the swim bladder wall) and radiates sound into the water (Zelick et al., 1999). Sprague and Luczkovich (2004) calculated that silver perch, of the family sciaenidae, can produce drumming sounds ranging from 128 to 135 decibels (dB) referenced to 1 micropascal (dB re 1 µPa). Female midshipman fish apparently detect and locate the "hums" (approximately 90–400 Hz) of vocalizing males during the breeding season (McIver et al., 2014; Sisneros & Bass, 2003). Sciaenids produce a variety of sounds, including calls produced by males on breeding grounds (Ramcharitar et al., 2001), and a "drumming" call produced during chorusing that suggests a seasonal pattern to reproductive-related function (McCauley & Cato, 2000). Other sounds produced by chorusing reef fishes include "popping," "banging," and "trumpet" sounds; altogether, these choruses produce sound levels 35 dB above background levels, at peak frequencies between 250 and 1,200 Hz, and source levels between 144 and 157 dB re 1 µPa (McCauley & Cato, 2000).

Additional research using visual surveys (such as baited underwater video) and passive acoustic monitoring continue to reveal new sounds produced by fishes, both in the marine and freshwater environments, and allow for specific behaviors to be paired with those sounds (Radford et al., 2018; Rountree et al., 2018; Rowell et al., 2018).

3.9.1.2 General Threats

A summary of the major threats to fish species within the Study Area is described in the 2015 MITT Final EIS/OEIS. Overfishing and associated factors, such as bycatch, fisheries-induced evolution, and intrinsic vulnerability to overfishing were described. Pollution, including the effect of oceanic circulation patterns scattering coastal pollution throughout the open ocean, was described. The effects of organic and inorganic pollutants to fishes, including bioaccumulation of pollutants, behavioral and physiological changes, or genetic damage, were described, as well as entanglement in abandoned commercial and recreational fishing gear. Other human-caused stressors on fishes described were the introduction of non-native species, climate change, aquaculture, energy production, vessel movement, and underwater noise. Neither the extent or any other threats have changed since it was last described in the 2015 MITT Final EIS/OEIS. Therefore, the information and analysis presented in the 2015 MITT Final EIS/OEIS remains valid.

3.9.1.3 Endangered Species Act Species

The scalloped hammerhead shark (*Sphyrna lewini*), oceanic whitetip shark (*Carcharhinus longimanus*), and giant manta ray (*Manta birostris*) are the only ESA-listed fish species in the Study Area (Table 3.9-1). Two species of concern, the humphead wrasse (*Cheilinus undulates)* and bumphead parrotfish (*Bolbometopon muricatum*), also occur in the Study Area (Table 3.9-1). The National Marine Fisheries Service (NMFS) has some concerns regarding status and threats for species of concern, but insufficient information is available to indicate a need to list the species under the ESA. Species of concern status does not carry any procedural or substantive protections under the ESA. All the species listed in Table 3.9-1 are declining because of impacts from fishing (including night spear fishing, bycatch, and illegal fishing activities) and habitat degradation.

Table 3.9-1: Endangered Species Act Listed and Special Status Fish Species in the Mariana Islands Study Area

Species Name and Regulatory Status			Presence in Study Area	
Common Name	**Scientific Name**	**Endangered Species Act Status**	**Open Ocean/ Transit Corridor**	**Coastal Ocean**
Scalloped hammerhead shark (Indo-West Pacific Distinct Population Segment)	*Sphyrna lewini*	Threatened	Yes	Yes
Oceanic whitetip shark	*Carcharhinus longimanus*	Threatened	Yes	Yes
Giant manta ray	*Manta birostris*	Threatened	Yes	Yes
Humphead wrasse	*Cheilinus undulatus*	Species of Concern	No	Yes
Bumphead parrotfish	*Bolbometopon muricatum*	Species of Concern	No	Yes

3.9.1.3.1 Scalloped Hammerhead Shark (*Sphyrna lewini*)

A literature review found that the information on the scalloped hammerhead shark in the Study Area has not substantially changed from what is included in the 2015 MITT Final EIS/OEIS. Therefore, the information presented in the 2015 MITT Final EIS/OEIS remains valid.

3.9.1.3.1.1 Status and Management

In 2013, NMFS determined that two distinct population segments, the Central and Southwest Atlantic and Indo-West Pacific, warrant listing as threatened. The Indo-West Pacific distinct population segment is the only one located within the Study Area. Following a review of recent literature, the status and management of this species has not changed since the publication of the 2015 MITT Final EIS/OEIS. As such, the information and analysis presented in the 2015 MITT Final EIS/OEIS remains valid. No critical habitat has been designated for this species.

3.9.1.3.1.2 Habitat and Geographic Range

The habitat and geographic range of scalloped hammerhead sharks is described in the 2015 MITT Final EIS/OEIS. Following a review of recent literature, information related to habitat and the geographic range of this species has not changed since the publication of the 2015 MITT Final EIS/OEIS. As such, the information and analysis presented in the 2015 MITT Final EIS/OEIS remains valid.

3.9.1.3.1.3 Population and Abundance

As indicated in the 2015 MITT Final EIS/OEIS, information on population and abundance of scalloped hammerhead sharks is limited. Following a review of recent literature, information related to population

and abundance estimates for this species has not changed since the publication of the 2015 MITT Final EIS/OEIS. As such, the information and analysis presented in the 2015 MITT Final EIS/OEIS remains valid.

3.9.1.3.1.4 Predator and Prey Interactions

A new study by Brown et al. (2016) found that juvenile scalloped hammerhead sharks in the Rewa River estuary on Fiji consumed primarily estuarine and marine prawns, stomatopoda (mantis shrimps), estuarine eels, and various bony fish, with prawns being found in half of the stomachs sampled, which is consistent with other available information. However, this new information does not appreciably change the information and analysis that was presented in the 2015 MITT Final EIS/OEIS.

3.9.1.3.1.5 Species-Specific Threats

Primary threats to scalloped hammerhead sharks are from direct take, especially by the foreign commercial shark fin fishery (National Marine Fisheries Service, 2011), as described in the 2015 MITT Final EIS/OEIS. Following a review of recent literature, information on threats to this species has not changed since the publication of the 2015 MITT Final EIS/OEIS. As such, the information and analysis presented in the 2015 MITT Final EIS/OEIS remains valid.

3.9.1.3.2 Oceanic Whitetip Shark (*Carcharhinus longimanus*)

3.9.1.3.2.1 Status and Management

Since the publication of the 2015 MITT Final EIS/OEIS, NMFS proposed on December 29, 2016 to list the oceanic whitetip shark as a threatened species under the ESA (81 Federal Register [FR] 96304). On January 30, 2018, NMFS published the Final Rule listing this species as threatened and concluded that critical habitat is not determinable because data sufficient to perform the required analyses are lacking (83 FR 4153). Because this species was proposed as threatened, and subsequently listed as threatened under the ESA after the publication of the 2015 MITT Final EIS/OEIS, the impact analysis included in Section 3.9.2 (Environmental Consequences) is new.

3.9.1.3.2.2 Habitat and Geographic Range

Oceanic whitetip sharks are found worldwide in warm tropical and subtropical waters between 30° North and 35° South latitude near the surface of the water column (Young et al., 2016). Oceanic whitetips occur throughout the Central Pacific. This species has a clear preference for open ocean waters, with abundances decreasing with greater proximity to continental shelves. Preferring warm waters near or over 20°Celsius (68°Fahrenheit), and offshore areas, the oceanic whitetip shark is known to undertake seasonal movements to higher latitudes in the summer (National Oceanic and Atmospheric Administration, 2016b) and may regularly survey extreme environments (deep depths, low temperatures) as a foraging strategy (Young et al., 2016).

3.9.1.3.2.3 Population and Abundance

Population trend information is not clear or available. Information shows that the population has declined and there is evidence of decreasing average weights of the sharks. Unstandardized nominal catch data from the Inter-American Tropical Tuna Commission in the eastern Pacific tropical tuna purse seine fisheries show trends of decreasing catch (Inter-American Tropical Tuna Commission, 2015). In addition, Rice & Harvey (2012) found catch, catch per unit effort, and size composition data for oceanic whitetip sharks in the western and central Pacific all show consistent declines.

3.9.1.3.2.4 Predator and Prey Interactions

Oceanic whitetip sharks are large, often reaching a maximum length of 345 centimeters (cm) (Ebert et al., 2015), can live up to nine years (Joung et al., 2016), and are one of the major apex predators in the tropical open ocean waters. This species feeds on fishes, stingrays, sea turtles, birds, and cephalopods, and has no known predators.

3.9.1.3.2.5 Species-Specific Threats

Threats include pelagic longline and drift net fisheries bycatch, targeted fisheries (for the shark fin trade), and destruction or modification of its habitat and range (Baum et al., 2015; Defenders of Wildlife, 2015b). Legal and illegal fishing activities have caused significant population declines for the oceanic whitetip shark caught as bycatch in tuna and swordfish longlines throughout its range.

3.9.1.3.3 Giant Manta Ray (*Manta birostris*)

3.9.1.3.3.1 Status and Management

Since the publication of the 2015 MITT Final EIS/OEIS, NMFS proposed on January 12, 2017 to list the giant manta ray as a threatened species under ESA (82 FR 3694). Based on the best scientific and commercial information available, including the status review report (Miller & Klimovich, 2016), and after taking into account efforts being made to protect these species, NMFS determined that the giant manta ray is likely to become an endangered species within the foreseeable future throughout a significant portion of its range. On January 22, 2018, NMFS published the Final Rule listing this species as threatened and concluded that critical habitat was not determinable because data sufficient to perform the required analyses are lacking (83 FR 2916). Because this species was proposed as threatened and subsequently listed as threatened under the ESA after the publication of the 2015 MITT Final EIS/OEIS, the impact analysis presented below in Section 3.9.2 (Environmental Consequences) is new.

3.9.1.3.3.2 Habitat and Geographic Range

Giant manta rays are visitors to productive coastlines with regular upwelling, including oceanic island shores, and offshore pinnacles and seamounts. They utilize sandy bottom habitat and seagrass beds, as well as shallow reefs, and the ocean surface both inshore and offshore. The species ranges globally and is distributed in tropical, subtropical, and temperate waters. They migrate seasonally usually more than 1,000 kilometers (km) (621.4 miles), however not likely across ocean basins (National Oceanic and Atmospheric Administration, 2016a).

3.9.1.3.3.3 Population and Abundance

No stock assessments exist for the giant manta ray. Most estimates of subpopulations are based on anecdotal observations by divers and fishermen, with current populations estimated between 100 and 1,500 individuals (Miller & Klimovich, 2016). In general, giant manta ray populations have declined, except in areas where they are specifically protected, such as the Hawaiian Islands (National Oceanic and Atmospheric Administration, 2016a). Giant manta rays reach maturity at age 10 and have one pup every two to three years (National Oceanic and Atmospheric Administration, 2016a).

3.9.1.3.3.4 Predator and Prey Interactions

Manta rays prey exclusively on plankton (Defenders of Wildlife, 2015a). The gill plates of the giant manta ray filters the water as they swim, straining out any plankton that is larger than a grain of sand (Defenders of Wildlife, 2015a).

3.9.1.3.3.5 Species-Specific Threats

Threats to giant manta rays include fisheries and bycatch, destruction or modification of habitat, and disease and predation. The international market highly values the gill plates of the giant manta ray for use in traditional medicines. They also trade their cartilage and skins and consume the manta ray meat or use it for local bait. Bycatch occurs in purse seine, gillnet, and trawl fisheries as well (National Oceanic and Atmospheric Administration, 2016a). Fisheries exist outside the Study Area in Indonesia, Sri Lanka, India, Peru, Mexico, China, Mozambique, and Ghana (Food and Agriculture Organization of the United Nations, 2013). Other potential threats include degradation of coral reefs, interaction with marine debris, marine pollution, and boat strikes (Food and Agriculture Organization of the United Nations, 2013).

3.9.1.4 Federally Managed Species

The Magnuson-Stevens Fishery Conservation and Management Act (MSA) (see Section 3.0.1.1, Federal Statutes, in the 2015 MITT Final EIS/OEIS) established eight fishery management councils that share authority with NMFS to manage and conserve the fisheries in federal waters. Together with NMFS, the councils maintain fishery management plans for species or species groups to regulate commercial and recreational fishing within their geographic regions. The Study Area is under the jurisdiction of the Western Pacific Regional Fishery Management Council. Sections 3.3 (Marine Habitats), 3.7 (Marine Vegetation), and 3.8 (Marine Invertebrates) analyze impacts on habitats within the Study Area.

The Mariana Archipelago Fishery Ecosystem Plan (FEP), which includes fishery management measures for Guam and the Commonwealth of the Northern Mariana Islands, was approved in 2009 and codified in 2010. The Western Pacific Regional Fishery Management Council is currently working on an update to the FEP (Western Pacific Regional Fishery Management Council, 2016). Federally managed fish species listed in the 2015 MITT Final EIS/OEIS and in Table 3.9-2 have not changed since the publication of the EIS/OEIS and the information and analysis presented in the 2015 MITT Final EIS/OEIS remains valid.

The 2015 NMFS stock assessment report for the bottomfish fishery in Guam and the Commonwealth of the Northern Mariana Islands (CNMI) concluded that the fishery was not overfished through 2013, and modeled projections predicted that the fishery was very unlikely to become overfished by 2017 (Yau et al., 2016). However, coral reef fisheries, which support most traditional fishing in the Study Area, have declined over the past 30 years (Weijerman et al., 2016). However, the catch from the non-commercial reef fish fishery in the CNMI, which supports most traditional fishing, has historically been underestimated, yet has clearly been in decline since the late 1970s (Cuetos-Bueno & Houk, 2014). Detailed information on overfished stocks is presented in Section 3.12.1.2 (Commercial and Recreational Fishing).

Table 3.9-2: Federally Managed Fish Species Within the Mariana Islands Study Area for Each Fishery Management Unit in the FEP

Western Pacific Regional Fishery Management Council	
Marianas Bottomfish Management Unit	
Common Name	**Scientific Name**
Amberjack	*Seriola dumerili*
Black trevally/jack	*Caranx lugubris*
Blacktip grouper	*Epinephelus fasciatus*
Blueline snapper	*Lutjanus kasmira*
Giant trevally/jack	*Caranx ignobilis*
Gray snapper	*Aprion virescens*
Lunartail grouper	*Variola louti*
Pink snapper	*Pristipomoides filamentosus*
Pink snapper	*Pristipomoides flavipinnis*
Red snapper/silvermouth	*Aphareus rutilans*
Red snapper/buninas agaga	*Etelis carbunculus*
Red snapper/buninas	*Etelis coruscans*
Redgill emperor	*Lethrinus rubrioperculatus*
Snapper	*Pristipomoides zonatus*
Yelloweye snapper	*Pristipomoides flavipinnis*
Yellowtail snapper	*Pristipomoides auricilla*

3.9.1.5 Taxonomic Group Descriptions

A literature review found that the information on the taxonomic groups of fishes in the Study Area has not substantially changed from what is included in the 2015 MITT Final EIS/OEIS. Therefore, the information presented in the 2015 MITT Final EIS/OEIS remains valid.

3.9.2 Environmental Consequences

In the Proposed Action for this SEIS/OEIS, there have been some modifications to the quantity and type of acoustic and explosive stressors under the two action alternatives. There are also additional species listed under the ESA that are considered. In addition, within the stressor framework presented in the

2015 MITT Final EIS/OEIS, high-energy lasers are being analyzed as a new energy stressor, as detailed in Section 3.0.4.3.2.2 (High-Energy Lasers).

The 2015 MITT Final EIS/OEIS considered training and testing activities that currently occur in the Study Area and considered all potential stressors related to fishes. The potential impacts on fishes in the Study Area from Navy training and testing activities is presented in detail for ESA-listed and federally managed species, as well as generally for taxonomic groups.

The stressors vary in intensity, frequency, duration, and location within the Study Area. The stressors applicable to fishes in the Study Area are the same stressors analyzed in the 2015 MITT Final EIS/OEIS and include:

- **Acoustic** (sonar and other transducers, vessel noise, aircraft noise, and weapon noise)
- **Explosives** (in-air explosions and in-water explosions)
- **Energy** (in-water electromagnetic devices and high-energy lasers)
- **Physical disturbance and strikes** (vessels, in-water devices, military expended materials, and seafloor devices)
- **Entanglement** (wires and cables, decelerators/parachutes)
- **Ingestion** (military expended materials – munitions, military expended materials other than munitions)
- **Secondary** (impacts associated with sediments and water quality)

This section evaluates how and to what degree potential impacts on fishes from stressors described in Section 3.0 (Introduction) may have changed since the analysis presented in the 2015 MITT Final EIS/OEIS was completed. Table 2.5-1 and Table 2.5-2 in Chapter 2 (Description of Proposed Action and Alternatives) list the proposed training and testing activities and include the number of times each activity would be conducted annually and the locations within the Study Area where the activity would typically occur under each alternative. The tables also present the same information for activities described in the 2015 MITT Final EIS/OEIS so that the proposed levels of training and testing under this SEIS/OEIS can be easily compared.

The Navy conducted a review of federal and state regulations and standards relevant to fishes and reviewed scientific literature published since 2015 for new information on fishes that could update the analysis presented in the 2015 MITT Final EIS/OEIS. The analysis presented in this section also considers standard operating procedures, which are discussed in Section 2.3.3 (Standard Operating Procedures) of this SEIS/OEIS, and mitigation measures that are described in Chapter 5 (Mitigation). The Navy would implement these measures to avoid or reduce potential impacts on fishes from stressors associated with the proposed training and testing activities. Mitigation for ESA-listed fishes will be coordinated with NMFS through the ESA consultation process.

3.9.2.1 Acoustic Stressors

The analysis of effects to fishes follows the concepts outlined in Section 3.0.4.7 (Conceptual Framework for Assessing Effects from Acoustic and Explosive Activities). This section begins with a summary of relevant data regarding acoustic impacts on fishes in Section 3.9.2.1.1 (Background). This is followed by an analysis of estimated impacts on fishes due to specific Navy acoustic stressors (sonar and other transducers, vessel noise, aircraft noise, and weapon noise). Additional explanations of the acoustic terms and sound energy concepts used in this section are found in Appendix H (Acoustic and Explosive Concepts).

The Navy will rely on the 2015 MITT Final EIS/OEIS analysis for the analysis of vessel noise and weapon noise, as there has been no substantive or otherwise meaningful change in the action, although new applicable and emergent science in regard to these sub-stressors is presented in the sections that follow. Due to available new literature, adjusted sound exposure criteria, and new acoustic effects modeling, the analysis provided in Section 3.9.2.1.2 (Impacts from Sonar and Other Transducers) and Section 3.9.2.1.4 (Impacts from Aircraft Noise) of this SEIS/OEIS supplants the 2015 MITT Final EIS/OEIS for fishes, and changes estimated impacts for some species since the 2015 MITT Final EIS/OEIS.

3.9.2.1.1 Background

Effects of human-generated sound on fishes have been examined in numerous publications (Hastings & Popper, 2005; Hawkins et al., 2015; Ladich & Popper, 2004; Lindseth & Lobel, 2018; Mann, 2016; Mickle & Higgs, 2018; National Research Council, 1994, 2003; Neenan et al., 2016; Popper et al., 2004; Popper & Hawkins, 2019; Popper, 2003, 2008; Popper & Hastings, 2009b; Popper et al., 2014; Popper et al., 2016; Popper & Hawkins, 2018). The potential impacts from Navy activities are based on the analysis of available literature related to each type of effect. Where applicable, thresholds and relative risk factors presented in the *ANSI Sound Exposure Guideline* technical report (Popper et al., 2014) were used to assist in the analysis of effects on fishes from Navy activities.

There are limited studies of fish responses to aircraft and weapon noise. Based on the general characteristics of these sound types, for stressors where data is lacking (such as aircraft noise), studies of the effects of similar non-impulsive/continuous noise sources (such as sonar or vessel noise) are used to inform the analysis of fish responses. Similarly, studies of the effects from impulsive sources (such as air guns or pile driving) are used to inform fish responses to other impulsive sources (such as weapon noise). Non-impulsive or continuous sources may be presented as a proxy source to better understand potential reactions from fish where data from sonar and vessel noise exposures are limited. Additional information on the acoustic characteristics of these sources can be found in Appendix H (Acoustic and Explosive Concepts).

3.9.2.1.1.1 Injury

Injury refers to the direct effects on the tissues or organs of a fish. Moderate- to low-level noise from vessels, aircraft, and weapons use are described in Section 3.0.4.1 (Acoustic Stressors) and lacks the amplitude and energy to cause any direct injury. Section 3.0.4.7 (Conceptual Framework for Assessing Effects from Acoustic and Explosive Activities) provides additional information on injury and the framework used to analyze this potential impact.

Injury Due to Impulsive Sound Sources

Impulsive sounds, such as those produced by seismic air guns and impact pile driving, may cause injury or mortality in fishes. Although air guns and pile driving would not occur in the Study Area, this information aids in the analysis of other impulsive sources (i.e., weapons noise or in some cases, explosions). Mortality and potential damage to the cells of the lateral line have been observed in fish larvae, fry, and embryos after exposure to single shots from a seismic air gun within close proximity to the sound source (0.1 to 6 meters [m]) (Booman et al., 1996; Cox et al., 2012). However, exposure of adult fish to a single shot from an air gun array (four air guns) within similar ranges (6 m), has not resulted in any signs of mortality within seven days after exposure (Popper et al., 2016). Although injuries occurred in adult fishes, they were similar to injuries seen in control subjects (i.e., fishes that were not exposed to the air gun) so there is little evidence that the air gun exposure solely contributed to the observed effects.

Injuries, such as ruptured swim bladders, hematomas, and hemorrhaging of other gas-filled organs, have been reported in fish exposed to a large number of simulated impact pile driving strikes with cumulative sound exposure levels up to 219 decibels referenced to 1 micropascal squared seconds (dB re 1 μPa^2-s) under highly controlled settings where fish were unable to avoid the source (Casper et al., 2012b; Casper et al., 2013a; Casper et al., 2013b; Halvorsen et al., 2011; Halvorsen et al., 2012a; Halvorsen et al., 2012b). However, it is important to note that these studies exposed fish to 900 or more strikes, as the studies aimed to evaluate the equal energy hypothesis, which suggests that the effects of a large single pulse of energy is equivalent to the effects of energy received from many smaller pulses (as discussed in Smith & Gilley, 2008). Halvorsen et al. (2011) and Casper et al. (2017) found that the equal energy hypothesis does not apply to effects of pile driving; rather, metrics relevant to injury could include, but not be limited to, cumulative sound exposure level, single strike sound exposure level, and number of strikes (Halvorsen et al., 2011). Furthermore, Casper et al. (2017) found the amount of energy in each pile strike and the number of strikes determines the severity of the exposure and the injuries that may be observed. For example, hybrid striped bass (white bass *Morone chrysops* x striped bass *M. saxaltilis*) exposed to fewer strikes with higher single strike sound exposure values resulted in a higher number of, and more severe, injuries than bass exposed to an equivalent cumulative sound exposure level that contained more strikes with lower single strike sound exposure values. This is important to consider when comparing data from pile driving studies to potential effects from an explosion. Although single strike peak sound pressure levels were reported during these experiments (at average levels of 207 dB re 1 µPa), the injuries were only observed during exposures to multiple strikes, therefore, it is anticipated that a peak value much higher than the measured values would be required to lead to injury in fishes exposed to a single strike, or explosion.

These studies included species both with and without swim bladders. The majority of fish that exhibited injuries were those with swim bladders. Lake sturgeon (*Acipenser fulvescens*), a physostomous fish, was found to be less susceptible to injury from impulsive sources than Nile tilapia (*Oreochromis niloticus*) or hybrid striped bass, physoclistous fishes (Casper et al., 2017; Halvorsen et al., 2012a). As reported by Halvorsen et al. (2012a), the difference in results is likely due to the type of swim bladder in each fish. Physostomous fishes have an open duct connecting the swim bladder to their esophagus and may be able to quickly adjust the amount of gas in their body by gulping or releasing air. Physoclistous fishes do not have this duct; instead, gas pressure or glands regulate gas pressure in the swim bladder. There were no mortalities reported during these experiments, and in the studies where recovery was observed, the majority of exposure related injuries healed within a few days in a laboratory setting. In many of these controlled studies, neutral buoyancy was determined in the fishes prior to exposure to the simulated pile driving. However, fishes with similar physiology to those described in these studies that are exposed to actual pile driving activities may show varying levels of injury depending on their state of buoyancy.

By exposing caged juvenile European sea bass (*Dicentrarchus labrax*) to actual pile driving operations, Debusschere et al. (2014) largely confirmed the results discussed in the paragraph above. No differences in mortality were found between control and experimental groups at similar levels tested in the experiments described in the paragraph above (sound exposure levels up to 215–222 dB re 1 μPa^2-s), and many of the same types of injuries occurred (Casper et al., 2012b; Casper et al., 2013a; Casper et al., 2013b; Halvorsen et al., 2011; Halvorsen et al., 2012a; Halvorsen et al., 2012b). Fishes with injuries from impulsive sources such as these may not survive in the wild due to harsher conditions and risk of predation.

Other potential effects from exposure to impulsive sound sources include potential bubble formation and neurotrauma. It is speculated that high sound pressure levels may also cause bubbles to form from micronuclei in the blood stream or other tissues of animals, possibly causing embolism damage (Hastings & Popper, 2005). Fishes have small capillaries where these bubbles could be caught and lead to the rupturing of the capillaries and internal bleeding. It has also been speculated that this phenomena could take place in the eyes of fish due to potentially high gas saturation within the eye tissues (Popper & Hastings, 2009b). Additional research is necessary to verify if these speculations apply to exposures to non-impulsive sources such as sonars. These phenomena have not been well studied in fishes and are difficult to recreate under real-world conditions.

As summarized in the *ANSI Sound Exposure Guideli*ne technical report (Popper et al., 2014), exposure to high intensity and long duration impact pile driving or air gun shots did not cause mortality, and fishes typically recovered from injuries in controlled laboratory settings. Species tested to date can be used as viable surrogates for investigating injury in other species exposed to similar sources (Popper et al., 2014).

Injury due to Sonar and Other Transducers

Non-impulsive sound sources (e.g., sonar, acoustic modems, and sonobuoys) have not been known to cause direct injury or mortality to fish under conditions that would be found in the wild (Halvorsen et al., 2012a; Kane et al., 2010; Popper et al., 2007). Potential direct injuries (e.g., barotrauma, hemorrhage or rupture of organs or tissue) from non-impulsive sound sources, such as sonar, are unlikely because of slow rise times,[1] lack of a strong shock wave such as that associated with an explosive, and relatively low peak pressures. General categories and characteristics of Navy sonar systems are described in Section 3.0.4.1.1 (Sonar and Other Transducers).

The effects of mid-frequency sonar-like signals (1.5−6.5 kHz) on larval and juvenile Atlantic herring (*Clupea harengus*), Atlantic cod (*Gadus morhua*), saithe (*Pollachius virens*), and spotted wolffish (*Anarhichas minor*) were examined by Jørgensen et al. (2005).Researchers investigated potential effects on survival, development, and behavior in this study. Among fish kept in tanks and observed for one to four weeks after sound exposure, no significant differences in mortality or growth-related parameters between exposed and unexposed groups were observed. Examination of organs and tissues from selected herring experiments did not reveal obvious differences between unexposed and exposed groups. However, two (out of 42) of the herring groups exposed to sound pressure levels of 189 dB re 1 µPa and 179 dB re 1 µPa had a post-exposure mortality of 19 and 30 percent, respectively. It is not clear if this increased mortality was due to the received level or to other unknown factors, such as exposure to the resonance frequency of the swim bladder. Jørgensen et al. (2005) estimated a resonant frequency of 1.8 kHz for herring and saithe ranging in size from 6.3 to 7.0 cm, respectively, which lies within the range of frequencies used during sound exposures and therefore may explain some of the noted mortalities.

Individual juvenile fish with a swim bladder resonance in the frequency range of the operational sonars may be more susceptible to injury or mortality. Past research has demonstrated that fish species, size,

[1] Rise time: the amount of time for a signal to change from static pressure (the ambient pressure without the added sound) to high pressure. Rise times for non-impulsive sound typically have relatively gradual increases in pressure, while impulsive sound has near-instantaneous rise to a high peak pressure. For more detail, see Appendix H (Acoustic and Explosive Concepts).

and depth influences resonant frequency (Løvik & Hovem, 1979; McCartney & Stubbs, 1971). At resonance, the swim bladder, which can amplify vibrations that reach the fish's hearing organs, may absorb much of the acoustic energy in the impinging sound wave. It is suspected that the resulting oscillations may cause mortality, harm the auditory organs or the swim bladder (Jørgensen et al., 2005; Kvadsheim & Sevaldsen, 2005b). However, damage to the swim bladder and to tissues surrounding the swim bladder was not observed in fishes exposed to sonar at their presumed swim bladder resonant frequency (Jørgensen et al., 2005). Sonar is expected to physiologically affect adult fish less than juveniles because adult fish are in a more robust stage of development, and their swim bladder resonant frequencies would be lower than that of mid-frequency active sonar. Additionally, adult fish have more ability to move from an unpleasant stimulus (Kvadsheim & Sevaldsen, 2005a). Lower frequencies (i.e., generally below 1 kHz) are expected to produce swim bladder resonance in adult fishes from about 10 to 100 centimeters (McCartney & Stubbs, 1971). Fish, especially larval and small juveniles, are more susceptible to injury from swim bladder resonance when exposed to continuous signals within the resonant frequency range.

Hastings (1991; 1995) tested the limits of acoustic exposure on two freshwater fish species. Hastings found "acoustic stunning" (loss of consciousness) in blue gouramis (*Trichogaster trichopterus*) following an eight-minute continuous exposure in captivity to a 150 Hz pure tone with a sound pressure level of 198 dB re 1 µPa (Hastings, 1995). This species of fish has an air bubble in the mouth cavity directly adjacent to the animal's braincase that may have caused this injury. Hastings (1991; 1995) also found that goldfish (*Carassius auratus*) exposed to a 250 Hz continuous wave sound with peak pressures of 204 dB re 1 µPa for two hours and blue gourami exposed to a 150 Hz continuous wave sound at a sound pressure level of 198 dB re 1 µPa for 0.5 hour did not survive. These studies illustrate the highest-known levels tested on fishes with hearing specializations. These high levels of noise were also projected for relatively long durations of time and in a small tank test environment, therefore direct comparisons to results in natural settings should be treated with caution. Stunning and mortality due to exposure to non-impulsive sound exposure has not been observed in other studies.

Three freshwater species of fish, the rainbow trout (*Oncorhynchus mykiss*), channel catfish (*Ictalurus punctatus*), and the hybrid sunfish (*Lepomis* sp.), were exposed to both low- and mid-frequency sonar (Kane et al., 2010; Popper et al., 2007). Low-frequency exposures with received sound pressure levels of 193 dB re 1 µPa occurred for either 324 or 648 seconds. Mid-frequency exposures with received sound pressure levels of 210 dB re 1 µPa occurred for 15 seconds. No fish mortality resulted from either experiment, and during necropsy after test exposures, both studies found that none of the subjects showed signs of tissue damage related to exposure (Kane et al., 2010; Popper et al., 2007).

As summarized in the *ANSI Sound Exposure Guideline* technical report (Popper et al., 2014), although fish have been injured and killed due to intense, long-duration, non-impulsive sound exposures, fish exposed under more realistic conditions have shown no signs of injury. Those species tested to date can be used as viable surrogates for estimating injury in other species exposed to similar sources.

3.9.2.1.1.2 Hearing Loss

Researchers have examined the effects on hearing in fishes from sonar-like signals, tones, and different non-impulsive noise sources. Section 3.0.4.7 (Conceptual Framework for Assessing Effects from Acoustic and Explosive Activities) provides additional information on hearing loss and the framework used to analyze this potential impact.

Exposure to high-intensity sound can cause hearing loss, also known as a noise-induced threshold shift, or simply a threshold shift (Miller, 1974). A temporary threshold shift (TTS) is a temporary, recoverable loss of hearing sensitivity. A TTS may last several minutes to several weeks, and the duration may be related to the intensity of the sound source and the duration of the sound (including multiple exposures). A permanent threshold shift (PTS) is non-recoverable, results from the destruction of tissues within the auditory system, permanent loss of hair cells, or damage to auditory nerve fibers (Liberman, 2016), and can occur over a small range of frequencies related to the sound exposure. However, the sensory hair cells of the inner ear in fishes are regularly replaced over time when they are damaged, unlike in mammals where sensory hair cells loss is permanent (Lombarte et al., 1993; Popper et al., 2014; Smith et al., 2006). Consequently, PTS has not been known to occur in fishes, and any hearing loss in fish may be as temporary as the timeframe required to repair or replace the sensory cells that were damaged or destroyed (Popper et al., 2005; Popper et al., 2014; Smith et al., 2006). (Popper et al., 2005; Popper et al., 2014; Smith et al., 2006). As with TTS, the animal does not become deaf but requires a louder sound stimulus, relative to the amount of PTS, to detect a sound within the affected frequencies. Although available data for some terrestrial mammals have shown signs of nerve damage after severe threshold shifts (e.g., Kujawa & Liberman, 2009; Lin et al., 2011), it is not known if damage to auditory nerve fibers could also occur in fishes and, if so, whether fibers would recover during this process. One example that demonstrated a lack of damage to sensory receptors when TTS occurred was in a study on hearing loss in zebrafish (*Danio rerio,* a freshwater species with a swim bladder involved in hearing). This was one of the first studies to look at both auditory threshold shifts and potential physical effects on the inner ear. However, marine species have yet to be tested and future research should evaluate other potential mechanisms of cellular or structural damage if in fact physical damage occurs in fishes with the onset of a threshold shift (Breitzler et al., 2020).

Hearing Loss due to Impulsive Sound Sources

Popper et al. (2005) examined the effects of a seismic air gun array on a fish with a swim bladder that is involved in hearing, the lake chub (*Couesius plumbeus*), and two species that have a swim bladder that is not involved in hearing, the northern pike (*Esox lucius*) and the broad whitefish (*Coregonus nasus*), a salmonid. In this study, the lowest received cumulative sound exposure level at which effects were noted was 186 dB re 1 μPa^2-s (5 shots with a mean sound pressure level of 177 dB re 1 µPa). The results showed temporary hearing loss for both lake chub and northern pike to both 5 and 20 air gun shots, but not for the broad whitefish. Hearing loss was approximately 20 to 25 dB at some frequencies for both species, and full recovery of hearing took place within 18 hours after sound exposure. Examination of the sensory surfaces of the ears after allotted recovery times (one hour for five shot exposures, and up to 18 hours for 20 shot exposures) showed no damage to sensory hair cells in any of the fish from these exposures (Song et al., 2008).

McCauley et al. (2003) and McCauley and Kent (2012) showed loss of a small percent of sensory hair cells in the inner ear of caged fish exposed to a towed air gun array simulating a passing seismic vessel. Pink snapper (*Pagrus auratus*), a species that has a swim bladder that is not involved in hearing, were exposed to multiple air gun shots for up to 1.5 hours (McCauley et al., 2003) where the maximum received sound exposure levels exceeded 180 dB re 1 μPa^2-s. The loss of sensory hair cells continued to increase for up to at least 58 days post exposure to 2.7 percent of the total cells. Gold band snapper (*Pristipomoides multidens*) and sea perch (*Lutjanis kasmira*), both fishes with a swim bladder involved in hearing, were also exposed to a towed air gun array simulating a passing seismic vessel (McCauley & Kent, 2012). Although received levels for these exposures have not been published, hair cell damage

increased as the range of the exposure (i.e., range to the source) decreased. Again, the amount of damage was considered small in each case (McCauley & Kent, 2012). It is not known if this hair cell loss would result in hearing loss since fish have tens or even hundreds of thousands of sensory hair cells in the inner ear and only a small portion were affected by the sound (Lombarte & Popper, 1994; Popper & Hoxter, 1984). A reason McCauley and Kent (2012) found damage to sensory hair cells while Popper et al. (2005) did not may be in their distinct methodologies. Their studies had many differences, including species and the precise sound source characteristics.

Hastings et al. (2008) exposed a fish with a swim bladder that is involved in hearing, the pinecone soldierfish (*Myripristis murdjan*), and three species that have a swim bladder that is not involved in hearing, the blue green damselfish (*Chromis viridis*), the saber squirrelfish (*Sargocentron spiniferum*), and the bluestripe seaperch (*Lutjanus kasmira*), to an air gun array. Fish in cages were exposed to multiple air gun shots with a cumulative sound exposure level of 190 dB re 1 μPa^2-s. The authors found no hearing loss in any fish examined up to 12 hours after the exposures.

In an investigation of another impulsive source, Casper et al. (2013b) found that some fishes may actually be more susceptible to barotrauma (e.g., swim bladder ruptures, herniations, and hematomas) than hearing effects when exposed to simulated impact pile driving. Hybrid striped bass (white bass x striped bass) and Mozambique tilapia (*Oreochromis mossambicus*), two species with a swim bladder not involved in hearing, were exposed to sound exposure levels between 213 and 216 dB re 1 μPa^2-s. The subjects exhibited barotrauma, and although researchers began to observe signs of inner ear hair cell loss, these effects were small compared to the other non-auditory injuries incurred. Researchers speculated that injury might occur prior to signs of hearing loss or TTS. These sound exposure levels may present the lowest threshold at which hearing effects may begin to occur.

Overall, PTS has not been known to occur in fishes tested to date. Any hearing loss in fish may be as temporary as the timeframe required to repair or replace the sensory cells that were damaged or destroyed (Popper et al., 2005; Popper et al., 2014; Smith et al., 2006). The lowest sound exposure level at which TTS has been observed in fishes with a swim bladder involved in hearing is 186 dB re 1 μPa^2-s. As reviewed in the *ANSI Sound Exposure Guideline* technical report (Popper et al., 2014), fishes without a swim bladder, or fishes with a swim bladder that is not involved in hearing, would be less susceptible to hearing loss (i.e., TTS) than fishes with swim bladders involved in hearing, even at higher levels and longer durations.

Hearing Loss due to Sonar and Other Transducers

Several studies have examined the effects of the sound exposures from low-frequency sonar on fish hearing (i.e., Halvorsen et al., 2013; Kane et al., 2010; Popper et al., 2007). Hearing was measured both immediately post exposure and for up to several days thereafter (Halvorsen et al., 2013; Kane et al., 2010; Popper et al., 2007). Maximum received sound pressure levels were 193 dB re 1 µPa for 324 or 648 seconds (a cumulative sound exposure level of 218 or 220 dB re 1 μPa^2-s, respectively) at frequencies ranging from 170 to 320 Hz (Kane et al., 2010; Popper et al., 2007), and 195 dB re 1 µPa for 324 seconds (a cumulative sound exposure level of 215 dB re 1 μPa^2-s) in a follow-on study (Halvorsen et al., 2013). Two species with a swim bladder not involved in hearing, the largemouth bass (*Micropterus salmoides*) and yellow perch (*Perca flavescens*), showed no loss in hearing sensitivity from sound exposure immediately after the test or 24 hours later. Channel catfish, a fish with a swim bladder involved in hearing, and some specimens of rainbow trout, a fish with a swim bladder not involved in hearing, showed a threshold shift (up to 10–20 dB of hearing loss) immediately after exposure to the low-frequency sonar when compared to baseline and control animals. Small thresholds shifts were

detected for up to 24 hours after the experiment in some channel catfish. Although some rainbow trout in one test group showed signs of hearing loss, rainbow trout in another group showed no hearing loss. The different results between rainbow trout test groups are difficult to understand, but may be due to development or genetic differences in the various groups of fish. Catfish hearing returned to, or close to, normal within about 24 hours after exposure to low-frequency sonar. Examination of the inner ears of the fish during necropsy revealed no differences from the control groups in ciliary bundles or other features indicative of hearing loss. The maximum time fish were held post exposure before sacrifice was 96 hours (Kane et al., 2010).

The same investigators examined the potential effects of mid-frequency active sonar on fish hearing and the inner ear (Halvorsen et al., 2012c; Kane et al., 2010). The maximum received sound pressure level was 210 dB re 1 µPa at a frequency of 2.8 to 3.8 kHz for a total duration of 15 seconds (cumulative sound exposure level of 220 dB re 1 μPa^2-s). Out of the species tested (rainbow trout and channel catfish), only one test group of channel catfish showed any hearing loss after exposure to mid-frequency active sonar. The investigators tested catfish during two different seasons and found that the group tested in October experienced TTS, which recovered within 24 hours, but fish tested in December showed no effect. It was speculated that the difference in hearing loss between catfish groups might have been due to the difference in water temperature during the testing period or due to differences between the two stocks of fish (Halvorsen et al., 2012c). Any effects on hearing in channel catfish due to sound exposure appeared to be short-term and non-permanent (Halvorsen et al., 2012c; Kane et al., 2010).

Some studies have suggested that there may be some loss of sensory hair cells due to high-intensity sources, indicating a loss in hearing sensitivity; however, none of those studies concurrently investigated the subjects' actual hearing range after exposure to these sources. Enger (1981) found loss of ciliary bundles of the sensory cells in the inner ears of Atlantic cod following one to five hours of exposure to pure tone sounds between 50 and 400 Hz with a sound pressure level of 180 dB re 1 µPa. Hastings (1995) found auditory hair-cell damage in goldfish, a freshwater species with a swim bladder that is involved in hearing. Goldfish were exposed to 250 Hz and 500 Hz continuous tones with maximum peak sound pressure levels of 204 dB re 1 µPa and 197 dB re 1 µPa, respectively, for about two hours. Similarly, Hastings et al. (1996) demonstrated damage to some sensory hair cells in oscars (*Astronotus ocellatus*) observed one to four days following a one-hour exposure to a pure tone at 300 Hz with a sound pressure level of 180 dB re 1 µPa, but no damage to the lateral line was observed. Both studies found a relatively small percentage of total hair cell loss from hearing organs despite long duration exposures. Effects from long-duration noise exposure studies are generally informative; however, they are not necessarily a direct comparison to intermittent short-duration exposures produced during Navy activities involving sonar and other transducers.

As noted in the *ANSI Sound Exposure Guideline* technical report (Popper et al., 2014), some fish species with a swim bladder that is involved in hearing may be more susceptible to TTS from high-intensity non-impulsive sound sources, such as sonar and other transducers, depending on the duration and frequency content of the exposure. Fishes with a swim bladder involved in hearing and fishes with high-frequency hearing may exhibit TTS from exposure to low- and mid-frequency sonar, specifically at cumulative sound exposure levels above 215 dB re 1 μPa^2-s. However, fishes without a swim bladder and fishes with a swim bladder that is not involved in hearing would be unlikely to detect mid-frequency or other higher-frequency sonars and would likely require a much higher sound exposure level to exhibit the same effect from exposure to low-frequency active sonar.

Hearing Loss due to Vessel Noise

Little data exist on the effects of vessel noise on hearing in fishes. However, TTS has been observed in fishes exposed to elevated background noise and other non-impulsive sources (e.g., white noise). Caged studies on pressure-sensitive fishes (i.e., fishes with a swim bladder involved in hearing and those with high-frequency hearing) show some hearing loss after several days or weeks of exposure to increased background sounds, although the hearing loss seems to recover (e.g., Scholik & Yan, 2002b; Smith et al., 2004b; Smith et al., 2006). Smith et al. (2004b; 2006) exposed goldfish, to noise with a sound pressure level of 170 dB re 1 µPa and found a clear relationship between the amount of hearing loss and the duration of exposure until maximum hearing loss occurred at about 24 hours of exposure. A 10-minute exposure resulted in 5 dB of TTS, whereas a three-week exposure resulted in a 28 dB TTS that took over two weeks to return to pre-exposure baseline levels (Smith et al., 2004b). Recovery times were not measured by investigators for shorter exposure durations. It is important to note that these exposures were continuous and subjects were unable to avoid the sound source for the duration of the experiment.

Scholik and Yan (2001) demonstrated TTS in fathead minnows (*Pimephales promelas*) after a 24-hour continuous exposure to white noise (0.3–2.0 kHz) at 142 dB re 1 µPa that took up to 14 days post-exposure to recover. This is the longest recorded time for a threshold shift to recover in a fish. The same authors also found that the bluegill sunfish (*Lepomis macrochirus*), a species that primarily detects particle motion and lacks specializations for hearing, did not show significant elevations in auditory thresholds when exposed to the same stimulus (Scholik & Yan, 2002a). This demonstrates again that fishes with a swim bladder involved in hearing and those with high-frequency hearing may be more sensitive to hearing loss than fishes without a swim bladder or those with a swim bladder not involved in hearing.

Breitzler et al. (2020) exposed zebrafish (a freshwater fish with a swim bladder involved in hearing) to 24 hours of white noise at various frequencies and sound levels. This is one of the first studies that measured hearing thresholds, physical damage (i.e., loss of hair cells), and recovery post-exposure. Overall, results were similar to those from previous studies. As the noise level increased, the amount of TTS observed in zebrafish also increased and frequencies that were most affected were those within the fishes best hearing sensitivity. Breitzler et al. (2020) also observed an increase in response latency in fish with TTS (i.e., the fish were slower to respond to auditory stimuli during hearing tests). Threshold shifts in fish exposed to 130 dB and 140 dB recovered within three days whereas it took up to 14 days for fish exposed to the highest exposure level (150 dB) to return to pre-exposure levels. Similarly, response latency was time dependent and sometimes took up to 14 days to recover to pre-exposure levels. The highest threshold shifts recorded also resulted in hair cell loss but, similar to the other effects measured in this study, hair cells returned to baseline levels within seven days post-exposure. This further demonstrates the ability for fish to rejuvenate hair cells and for hearing thresholds to recover to baseline levels without any evidence of PTS.

When reviewing results from these three studies, it is important to note that the fish were unable to avoid the sound source (e.g., held stationary in tubs or tanks) and were subject to long, continuous duration exposures (e.g., days to weeks). A direct comparison of these results to fish exposed to continuous sound sources in natural settings should be treated with caution. For example, fishes that are exposed to vessel noise in their natural environment, even in areas with high levels of vessel movement, would only be exposed for periods of short durations (e.g., seconds or minutes) as vessels pass by. Therefore, overall effects would not likely rise to the level of impact demonstrated in laboratory

studies. As summarized in the *ANSI Sound Exposure Guideline* technical report (Popper et al., 2014), some fish species with a swim bladder that is involved in hearing may be more susceptible to TTS from long duration continuous noise, such as broadband[2] white noise, depending on the duration of the exposure (thresholds are proposed based on continuous exposure of 12 hours). However, it is not likely that TTS would occur in fishes with a swim bladder not involved in hearing or in fishes without a swim bladder.

3.9.2.1.1.3 Masking

Masking refers to the presence of a noise that interferes with a fish's ability to hear biologically important sounds, including those produced by prey, predators, or other fishes. Masking occurs in all vertebrate groups and can effectively limit the distance over which an animal can communicate and detect biologically relevant sounds. Human-generated continuous sounds (e.g., some sonar, vessel or aircraft noise, and vibratory pile driving) have the potential to mask sounds that are biologically important to fishes. Researchers have studied masking in fishes using continuous masking noise, but masking due to intermittent, short-duty cycle sounds has not been studied. Section 3.0.4.7 (Conceptual Framework for Assessing Effects from Acoustic and Explosive Activities) provides additional information on masking and the framework used to analyze this potential impact.

Masking is likely to occur in most fishes due to varying levels of ambient or natural noise in the environment such as wave action, precipitation, or other animal vocalizations (Popper et al., 2014). Ambient noise during higher sea states in the ocean has resulted in elevated thresholds in several fish species (Chapman & Hawkins, 1973; Ramcharitar & Popper, 2004). Although the overall intensity or loudness of ambient or human-generated noise may result in masking effects in fishes, masking may be most problematic when human-generated signals or ambient noise levels overlap the frequencies of biologically important signals (Buerkle, 1968, 1969; Popper et al., 2014; Tavolga, 1974).

Wysocki and Ladich (2005) investigated the influence of continuous white noise exposure on the auditory sensitivity of two freshwater fish with notable hearing specializations for sound pressure detection, the goldfish and the lined Raphael catfish (*Platydoras costatus*), and a freshwater fish without notable specializations, the pumpkinseed sunfish (*Lepomis gibbosus*). For the goldfish and catfish, baseline thresholds were lower than masked thresholds. Continuous white noise with a sound pressure level of approximately 130 dB re 1 µPa at 1 m resulted in an elevated threshold of 23–44 dB within the subjects' region of best sensitivity between 500 and 1,000 Hz. There was less evidence of masking in the sunfish during the same exposures, with only a shift of 11 dB. Wysocki and Ladich (2005) suggest that ambient sound regimes may limit acoustic communication and orientation, especially in animals with notable hearing specializations for sound pressure detection.

Masking could lead to potential fitness costs depending on the severity of the reaction and the animal's ability to adapt or compensate during an exposure (de Jong et al., 2020; Radford et al., 2014; Slabbekoorn et al., 2010). For example, masking could result in changes in predator-prey relationships, potentially inhibiting a fish's ability to detect predators and therefore increase its risk of predation (Astrup, 1999; Mann et al., 1998; Simpson et al., 2015; Simpson et al., 2016). Masking may also limit the distance over which fish can communicate or detect important signals (Alves et al., 2016; Codarin et al.,

[2] A sound or signal that contains energy across multiple frequencies.

2009; Ramcharitar et al., 2001; Ramcharitar et al., 2006), including sounds emitted from a reef for navigating larvae (Higgs, 2005; Neenan et al., 2016). If the masking signal is brief (a few seconds or less), biologically important signals may still be detected, resulting in little effect to the individual. If the signal is longer in duration (minutes or hours) or overlaps with important frequencies for a particular species, more severe consequences may occur such as the inability to attract a mate and reproduce. Holt and Johnston (2014) were the first to demonstrate the Lombard effect in one species of fish, a potentially compensatory behavior where an animal increases the source level of its vocalizations in response to elevated noise levels. The Lombard effect is currently understood to be a reflex that may be unnoticeable to the animal or may lead to increased energy expenditure during communication.

The *ANSI Sound Exposure Guideline* technical report (Popper et al., 2014) highlights a lack of data that exists for masking by sonar but suggests that the narrow bandwidth and intermittent nature of most sonar signals would result in only a limited probability of any masking effects. In addition, most sonars (mid-, high-, and very high-frequency) are above the hearing range of most marine fish species, eliminating the possibility of masking for these species. In most cases, the probability of masking would further decrease with increasing distance from the sound source.

In addition, no data are available on masking by impulsive signals (e.g., impact pile driving and air guns) (Popper et al., 2014). Impulsive sounds are typically brief, lasting only fractions of a second, where masking could occur only during that brief duration of sound. Biological sounds can typically be detected between pulses within close distances to the source unless those biological sounds are similar to the masking noise, such as impulsive or drumming vocalizations made by some fishes (e.g., cod or haddock). Masking could also indirectly occur because of repetitive impulsive signals where the repetitive sounds and reverberations over distance may create a more continuous noise exposure.

Although there is evidence of masking because of exposure to vessel noise, the *ANSI Sound Exposure Guideline* technical report (Popper et al., 2014) does not present numeric thresholds for this effect. Instead, relative risk factors are considered, and it is assumed the probability of masking occurring is higher at near to moderate distances from the source (up to hundreds of meters) but decreases with increasing distance (Popper et al., 2014).

3.9.2.1.1.4 Physiological Stress

Section 3.0.4.7 (Conceptual Framework for Assessing Effects from Acoustic and Explosive Activities) provides additional information on physiological stress and the framework used to analyze this potential impact. A fish must first be able to detect a sound above its hearing threshold and above the ambient noise level before a physiological stress reaction can occur. The initial response to a stimulus is a rapid release of stress hormones into the circulatory system, which may cause other responses such as elevated heart rate and blood chemistry changes. Although an increase in background sound has been shown to cause stress in humans and animals, only a limited number of studies have measured biochemical responses by fishes to acoustic stressors (e.g., Goetz et al., 2015; Madaro et al., 2015; Remage-Healey et al., 2006; Smith et al., 2004a; Wysocki et al., 2006; Wysocki et al., 2007), and the results have varied. Stimuli that have been used to study physiological stress responses in fishes include predator vocalizations, non-impulsive or continuous, and impulsive noise exposures.

A stress response that has been observed in fishes is the production of cortisol (a stress hormone) when exposed to sounds such as boat noise, tones, or predator vocalizations. Nichols et al. (2015) found that giant kelpfish (*Heterostichus rostratus*) had increased levels of cortisol with increased sound level and intermittency of boat noise playbacks. Cod exposed to a short-duration upsweep (a tone that sweeps

upward across multiple frequencies) across 100–1,000 Hz had increases in cortisol levels, which returned to normal within one hour post-exposure (Sierra-Flores et al., 2015). Remage-Healey et al. (2006) found elevated cortisol levels in Gulf toadfish (*Opsanus beta*) exposed to low-frequency bottlenose dolphin sounds, but they observed no physiological change when they exposed toadfish to low-frequency "pops" produced by snapping shrimp.

A sudden increase in sound pressure level (i.e., presentation of a sound source) or an increase in overall background noise levels can increase hormone levels and alter other metabolic rates indicative of a stress response, such as increased ventilation and oxygen consumption (Pickering, 1981; Popper & Hastings, 2009a; Radford et al., 2016; Simpson et al., 2015; Simpson et al., 2016; Smith et al., 2004a, 2004b; Spiga et al., 2017). Similarly, reef fish embryos exposed to boat noise have demonstrated changes in morphological development and increases in heart rate, another indication of a physiological stress response, although survival rates were unchanged (Fakan & McCormick, 2019; Jain-Schlaepfer et al., 2018). Although results have varied, it has been shown that chronic or long-term (days or weeks) exposures of continuous man-made sounds can lead to a reduction in embryo viability (Sierra-Flores et al., 2015) and decreased growth rates (Nedelec et al., 2015).

However, not all species tested to date show these reactions. Smith et al. (2004a) found no increase in corticosteroid, a class of stress hormones, in goldfish exposed to a continuous, band-limited noise (0.1–10 kHz) with a sound pressure level of 170 dB re 1 µPa for one month. Wysocki et al. (2007) exposed rainbow trout to continuous band-limited noise with a sound pressure level of about 150 dB re 1 µPa for nine months with no observed stress effects. Growth rates and effects on the trout's immune systems were not significantly different from control animals held at a sound pressure level of 110 dB re 1 µPa.

Fishes may have physiological stress reactions to sounds that they can hear. Generally, stress responses are more likely to occur in the presence of potentially threatening sound sources, such as predator vocalizations, or the sudden onset of impulsive signals rather than from non-impulsive or continuous sources such as vessel noise or sonar. If an exposure is short, the stress responses are typically brief (a few seconds to minutes). In addition, research shows that fishes may habituate (i.e., learn to tolerate) to the noise that is being presented after multiple exposures or longer duration exposures that prove to be non-threatening. However, exposure to chronic noise sources can lead to more severe impacts over time, such as reduced growth rates which can lead to reduced survivability for an individual. It is assumed that any physiological response (e.g., hearing loss or injury) or significant behavioral response is also associated with a stress response.

3.9.2.1.1.5 Behavioral Reactions

Section 3.0.4.7 (Conceptual Framework for Assessing Effects from Acoustic and Explosive Activities) provides additional information on behavioral reactions and the framework used to analyze this potential impact. Behavioral reactions in fishes have been observed due to a number of different types of sound sources. The majority of research has been performed using air guns (including large-scale seismic surveys), sonar, and vessel noise. Fewer observations have been made on behavioral reactions to impact pile driving noise, although fish are likely to show similar behavioral reactions to any impulsive noise within or outside the zone for hearing loss and injury.

As with masking, a fish must first be able to detect a sound above its hearing threshold and above the ambient noise level before a behavioral reaction can occur. Most fishes can only detect low-frequency sounds, with the exception of a few species that can detect some mid and high frequencies (above 1 kHz).

Fish studies have identified the following behavioral reactions to sound: alteration of natural behaviors (e.g., startle or alarm), and avoidance (LGL Ltd Environmental Research Associates et al., 2008; McCauley et al., 2000; Pearson et al., 1992). In the context of this SEIS/OEIS, and to remain consistent with available behavioral reaction literature, the terms "startle," "alarm," "response," and "reaction" will be used synonymously.

In addition, observed behavioral effects to fish could include disruption or alteration of natural activities such as swimming, schooling, feeding, breeding, and migrating. Sudden changes in sound level can cause fish to dive, rise, or change swimming direction. However, some fish may learn to tolerate or habituate to repeated exposures and noise that seems threatening (e.g., Bruintjes et al., 2016; Currie et al., 2020; Nedelec et al., 2016b; Radford et al., 2016).

Research on behavioral reactions can be difficult to understand and interpret. For example, behavioral responses often times vary depending on the type of exposure and sound source present. Changes in sound intensity may be more important to a fishes' behavior than the maximum sound level. Some studies show that sounds that fluctuate in level or have intermittent pulse rates tend to elicit stronger responses from fish than even stronger sounds with a continuous level (Currie et al., 2020; Neo et al., 2014; Schwarz & Greer, 1984). It has also been suggested that unpredictable sounds that last for long durations may have the largest impact on behavioral responses (de Jong et al., 2020). Interpreting behavioral responses can also be difficult due to species-specific behavioral tendencies, motivational state (e.g., feeding or mating), an individual's previous experience, how resilient a species is to changes in their environment, and whether or not the fish are able to avoid the source (e.g., caged versus free-swimming subjects). Results from caged studies may not provide a clear understanding of how free-swimming fishes may react to the same or similar sound exposures (Hawkins et al., 2015).

Behavioral Reactions due to Impulsive Sound Sources

It is assumed that most species would react similarly to impulsive sources such as weapons noise and explosions. However, it is important to note that most data on behavioral reactions to impulsive sources is collected from studies using air guns and impact pile driving, sources that do not occur in the Study Area. Reactions include startle or alarm responses and increased swim speeds at the onset of impulsive sounds (Fewtrell & McCauley, 2012; Pearson et al., 1992; Roberts et al., 2016a; Spiga et al., 2017). Data on fish behavioral reactions exposed to impulsive sound sources is mostly limited to studies using caged fishes and the use of seismic air guns (Løkkeborg et al., 2012). Several species of rockfish (*Sebastes* species) in a caged environment exhibited startle or alarm reactions to seismic air gun pulses between peak-to-peak sound pressure levels of 180 dB re 1 µPa and 205 dB re 1 µPa (Pearson et al., 1992). More subtle behavioral changes were noted at lower sound pressure levels, including decreased swim speeds. At the presentation of the sound, some species of rockfish settled to the bottom of the experimental enclosure and reduced swim speed. Trevally (*Pseudocaranx dentex*) and pink snapper also exhibited alert responses as well as changes in swim depth, speed, and schooling behaviors when exposed to air gun noise (Fewtrell & McCauley, 2012). Both trevally and pink snapper swam faster and closer to the bottom of the cage at the onset of the exposure. However, trevally swam in tightly cohesive groups at the bottom of the test cages while pink snapper exhibited much looser group cohesion. These behavioral responses were seen during sound exposure levels as low as 147 up to 161 dB re 1 μPa^2-s but habituation occurred in all cases, either within a few minutes or within 30 minutes after the final air gun shot (Fewtrell & McCauley, 2012; Pearson et al., 1992).

Some studies have shown a lack of behavioral reactions to air gun noise. Herring exposed to an approaching air gun survey (from 27 to 2 km over six hours), resulting in single pulse sound exposure levels of 125–155 dB re 1 μPa^2-s, did not react by changing direction or swim speed (Pena et al., 2013). Although these levels are similar to those tested in other studies which exhibited responses (Fewtrell & McCauley, 2012), the distance of the exposure to the test enclosure, the slow onset of the sound source, and a strong motivation for feeding may have affected the observed response (Pena et al., 2013). In another study, Wardle et al. (2001) observed marine fish on an inshore reef before, during, and after an air gun survey at varying distances. The air guns were calibrated at a peak level of 210 dB re 1 µPa at 16 m and 195 dB re 1 µPa at 109 m from the source. Other than observed startle responses and small changes in the position of pollack, when the air gun was located within close proximity to the test site (within 10 m), they found no substantial or permanent changes in the behavior of the fish on the reef throughout the course of the study. Behavioral responses to impulsive sources are more likely to occur within near and intermediate (tens to hundreds of meters) distances from the source as opposed to far distances (thousands of meters) (Popper et al., 2014).

Unlike the previous studies, Slotte et al. (2004) used fishing sonar (38 kHz echo sounder) to monitor behavior and depth of blue whiting (*Micromesistius poutassou*) and Norwegian spring herring (*Claupea harengus L.*) spawning schools exposed to air gun signals. They reported that fishes in the area of the air guns appeared to go to greater depths after the air gun exposure compared to their vertical position prior to the air gun usage. Moreover, the abundance of animals 30–50 km away from the air guns increased during seismic activity, suggesting that migrating fish left the zone of seismic activity and did not re-enter the area until the activity ceased. It is unlikely that either species was able to detect the fishing sonar. However, it should be noted that these behavior patterns may have also been influenced by other variables such as motivation for feeding, migration, or other environmental factors (e.g., temperature, salinity, etc.) (Slotte et al., 2004).

Alterations in natural behavior patterns due to exposure to pile driving noise have not been studied as thoroughly, but reactions noted thus far are similar to those seen in response to seismic surveys. These changes in behavior include startle responses, changes in depth (in both caged and free-swimming subjects), increased swim speeds, changes in ventilation rates, changes in attention and anti-predator behaviors, and directional avoidance (e.g., Hawkins et al., 2014; Mueller-Blenkle et al., 2010; Neo et al., 2015; Roberts et al., 2016a; Spiga et al., 2017). The severity of response varied greatly by species and received sound pressure level of the exposure. For example, some minor behavioral reactions such as startle responses were observed during caged studies with a sound pressure level as low as 140 dB re 1 µPa (Neo et al., 2014). However, only some free-swimming fishes avoided pile driving noise at even higher sound pressure levels between 152 and 157 dB re 1 µPa (Iafrate et al., 2016). In addition, Roberts et al. (2016a) observed that although multiple species of free swimming fish responded to simulated pile driving recordings, not all responded consistently. In some cases, only one fish would respond while the others continued feeding from a baited remote underwater video. In other instances, various individual fish would respond to different strikes. The repetition rate of pulses during an exposure may also have an effect on what behaviors were noted and how quickly these behaviors recovered as opposed to the overall sound pressure or exposure level (Neo et al., 2014). Neo et al. (2014) observed slower recovery times in fishes exposed to intermittent sounds (similar to pile driving) compared to continuous exposures.

As summarized in the *ANSI Sound Exposure Guideline* technical report (Popper et al., 2014), species may react differently to the same sound source depending on a number of variables, such as the animal's life

stage or behavioral state (e.g., feeding, mating). Without specific data, it is assumed that fishes react similarly to all impulsive sounds outside the zone for hearing loss and injury. Observations of fish reactions to large-scale air gun surveys are informative, but not necessarily directly applicable to analyzing impacts from the short-term, intermittent use of all impulsive sources. It is assumed that fish have a high probability of reacting to an impulsive sound source within near and intermediate distances (tens to hundreds of meters), and a decreasing probability of reaction at increasing distances (Popper et al., 2014).

Behavioral Reactions due to Sonar and Other Transducers

Behavioral reactions to sonar have been studied both in caged and free-swimming fish, although results can oftentimes be difficult to interpret depending on the species tested and the study environment. Jørgensen et al. (2005) showed that caged cod and spotted wolf fish (*Anarhichas minor*) lacked any response to simulated sonar between 1 and 8 kHz. However, within the same study, reactions were seen in juvenile herring. It is likely that the sonar signals were inaudible to the cod and wolf fish (species that lack notable hearing specializations), but audible to herring (a species that has hearing capabilities in the frequency ranges tested).

Doksæter et al. (2009; 2012) and Sivle et al. (2012; 2014) studied the reactions of both wild and captive Atlantic herring to the Royal Netherlands Navy's experimental mid-frequency active sonar ranging from 1 to 7 kHz. The behavior of the fish was monitored in each study either using upward-looking echosounders (for wild herring) or audio and video monitoring systems (for captive herring). The source levels used within each study varied across all studies and exposures with a maximum received sound pressure level of 181 dB re 1 µPa and maximum cumulative sound exposure level of 184 dB re 1 μPa^2s. No avoidance or escape reactions were observed when herring were exposed to any sonar sources. Instead, significant reactions were noted at lower received sound levels of different non-sonar sound types. For example, dive responses (i.e., escape reactions) were observed when herring were exposed to killer whale feeding sounds at received sound pressure levels of approximately 150 dB re 1 µPa (Sivle et al., 2012). Startle responses were seen when the cages for captive herring were hit with a wooden stick and with the ignition of an outboard boat engine at a distance of one meter from the test pen (Doksaeter et al., 2012). It is possible that the herring were not disturbed by the sonar, were more motivated to continue other behaviors such as feeding, or did not associate the sound as a threatening stimulus. Based on these results (Doksaeter et al., 2009; Doksaeter et al., 2012; Sivle et al., 2012), Sivle et al. (2014) created a model in order to report on the possible population-level effects on Atlantic herring from active naval sonar. The authors concluded that the use of naval sonar poses little risk to populations of herring regardless of season, even when the herring populations are aggregated and directly exposed to sonar.

There is evidence that elasmobranchs (cartilaginous fish including sharks and rays) also respond to human-generated sounds. A number of researchers conducted experiments in which they played back sounds (e.g., pulsed tones below 1 kHz) and attracted a number of different shark species to the sound source (e.g., Casper et al., 2012a; Myrberg et al., 1976; Myrberg et al., 1969; Myrberg et al., 1972; Nelson & Johnson, 1972). The results of these studies showed that sharks were attracted to irregularly pulsed low-frequency sounds (below several hundred Hz), in the same frequency range of sounds that might be produced by struggling prey. However, abrupt and irregularly pulsed human-generated noise (0.2–10 kHz, with most energy below 1 kHz) resulted in withdrawal responses of certain shark species (Chapuis et al., 2019). Sharks are not known to be attracted to continuous signals or higher frequencies that they presumably cannot hear (Casper & Mann, 2006; Casper & Mann, 2009).

Only a few species of fishes can detect sonars above 1 kHz (see Section 3.9.1.1, Hearing and Vocalization), meaning that most fishes would not detect most mid-, high-, or very high-frequency Navy sonars. The few marine species that can detect above 1 kHz and have some hearing specializations may be able to better detect the sound and would therefore be more likely to react. However, researchers have found little reaction by adult fish in the wild to sonars within the animals' hearing range (Doksaeter et al., 2009; Doksaeter et al., 2012; Sivle et al., 2012). The *ANSI Sound Exposure Guideline* technical report (Popper et al., 2014) suggests that fish able to hear sonars would have a low probability of reacting to the source within near or intermediate distances (within tens to hundreds of meters) and a decreasing probability of reacting at increasing distances.

Behavioral Reactions due to Vessel Noise

Vessel traffic also contributes to the amount of noise in the ocean and has the potential to affect fishes. Several studies have demonstrated and reviewed avoidance responses by fishes (e.g., herring and cod) to the low-frequency sounds of vessels (De Robertis & Handegard, 2013; Engås et al., 1995; Handegard et al., 2003). Misund (1997) found that fish that were ahead of a ship and showed avoidance reactions did so at ranges of 50–150 m. When the vessel passed over them, some species of fish responded with sudden escape responses that included lateral avoidance or downward compression of the school.

As mentioned above, behavioral reactions are quite variable and depend on a number of factors such as (but not limited to) the type of fish, its life history stage, behavior, time of day, location, the type of vessel, and the sound propagation characteristics of the water column (Popper et al., 2014; Schwarz & Greer, 1984). Reactions to playbacks of continuous noise or passing vessels generally include basic startle and avoidance responses, as well as evidence of distraction and increased decision-making errors. Other specific examples of observed responses include increased group cohesion, increased distractions or evidence of modified attention, changes in vertical distribution in the water column, changes in swim speeds, distance traveled, as well as changes in feeding efficacy such as reduced foraging attempts and increased mistakes (i.e., lowered discrimination between food and non-food items) (e.g., Bracciali et al., 2012; De Robertis & Handegard, 2013; Handegard et al., 2015; McCormick et al., 2019; Nedelec et al., 2015; Nedelec et al., 2017a; Neo et al., 2015; Payne et al., 2015; Purser & Radford, 2011; Roberts et al., 2016a; Sabet et al., 2016; Simpson et al., 2015; Simpson et al., 2016; Voellmy et al., 2014a; Voellmy et al., 2014b).

Behavioral responses may also be dependent on the type of vessel that fish are exposed to. For example, juvenile damselfish (*Pomacentrus wardi*) exposed to sound from a two-stroke engine resulted in startle responses, reduction in boldness (increased time spent hiding, less time exhibiting exploratory behaviors), and space use (maximum distance ventured from shelter or traveled within the test enclosure), as well as slower and more conservative reactions to visual stimuli analogous to a potential predator. However, damselfish exposed to sound from a four-stroke engine generally displayed similar responses as control fish exposed to ambient noise (e.g., little or no change in boldness) (McCormick et al., 2018; McCormick et al., 2019). Although the two sound sources were very similar, the vessels powered by the four-stroke engine were of lower intensity compared to vessels powered by the two-stroke engine, which may explain the overall reduced response to this engine type.

Vessel noise has also led to changes in anti-predator responses, but these responses vary by species. During exposures to vessel noise, juvenile Ambon damselfish (*Pomacentrus amboinensis*) and European eels showed slower reaction times and lacked startle responses to predatory attacks, and subsequently showed signs of distraction and increased their risk of predation during both simulated and actual predation experiments (Simpson et al., 2015; Simpson et al., 2016). Spiny chromis (*Acanthochromis*

polyacanthus) exposed to chronic boat noise playbacks for up to 12 consecutive days spent less time feeding and interacting with offspring, and increased defensive acts. In addition, offspring survival rates were also lower at nests exposed to chronic boat noise playbacks versus those exposed to ambient playbacks (Nedelec et al., 2017b). This suggests that chronic or long-term exposures could have more severe consequences than brief exposures.

In contrast, larval Atlantic cod showed a stronger anti-predator response and were more difficult to capture during simulated predator attacks (Nedelec et al., 2015). There are also observations of a general lack of response to shipping and pile driving playback noise by grey mullet (*Chelon labrosus*) and the two-spotted goby (*Gobiusculus flavescens*) (Roberts et al., 2016b). Mensinger et al. (2018) found that Australian snapper located in a protected area showed no change in feeding behavior or avoidance during boat passes, whereas snapper in areas where fishing occurs startled and ceased feeding behaviors during boat presence. This supports that location and past experience also have an influence on whether fishes react.

Although behavioral responses such as those listed above were often noted during the onset of most sound presentations, most behaviors did not last long and animals quickly returned to baseline behavior patterns. In fact, in one study, when given the chance to move from a noisy tank (with sound pressure levels reaching 120–140 dB re 1 µPa) to a quieter tank (sound pressure levels of 110 dB re 1 µPa), there was no evidence of avoidance. The fish did not seem to prefer the quieter environment and continued to swim between the two tanks comparable to control sessions (Neo et al., 2015). However, many of these reactions are difficult to extrapolate to real world conditions due to the captive environment in which testing occurred.

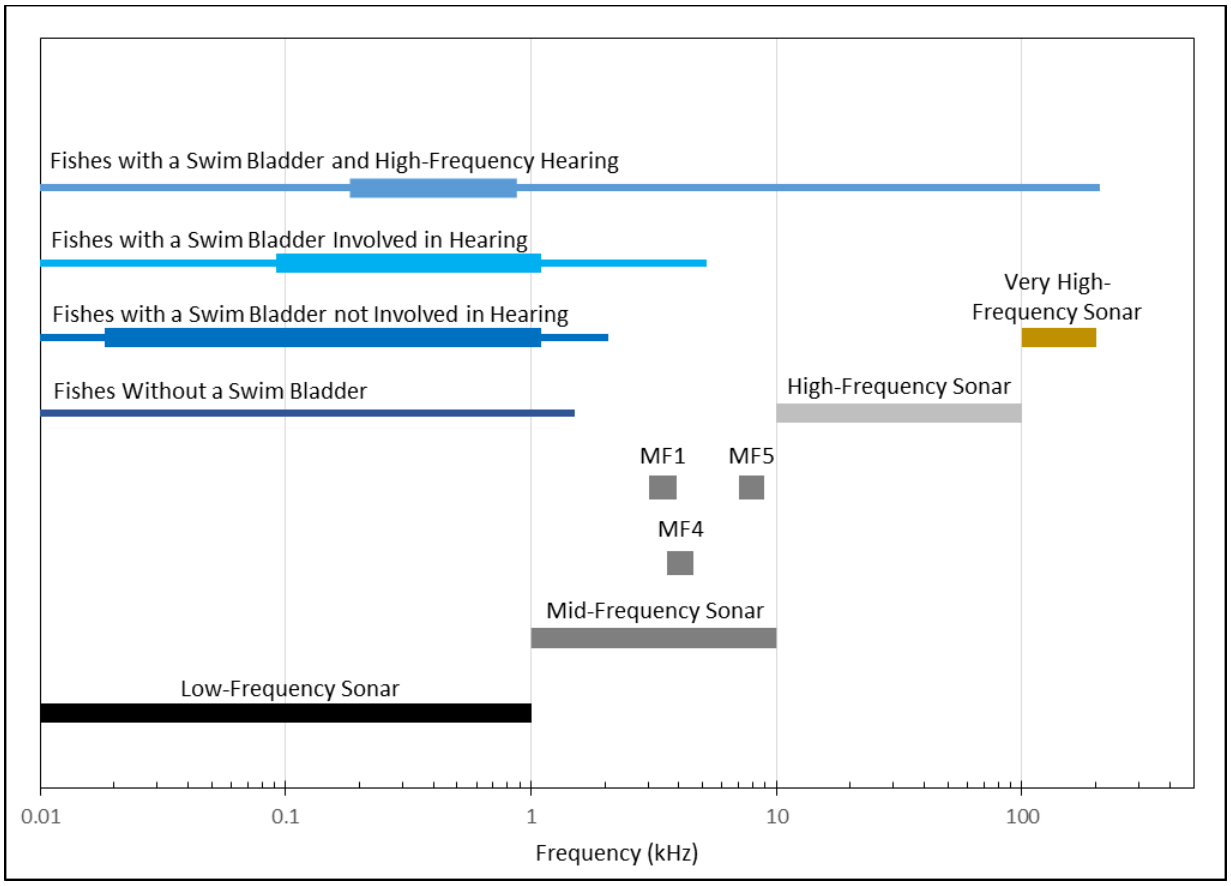
Most fish species should be able to detect vessel noise due to its low-frequency content and their hearing capabilities (see Section 3.9.1.1, Hearing and Vocalization). The *ANSI Sound Exposure Guideline* technical report (Popper et al., 2014) suggests that fishes have a moderate to high probability of reacting to nearby vessel noise (i.e., within tens of meters) with decreasing probability of reactions with increasing distance from the source (hundreds or more meters).

3.9.2.1.1.6 Long-Term Consequences

Section 3.0.4.7 (Conceptual Framework for Assessing Effects from Acoustic and Explosive Activities) provides additional information on potential pathways for long-term consequences. Mortality removes an individual fish from the population, while injury reduces the fitness of an individual. Few studies have been conducted on any long-term consequences from repeated hearing loss, stress, or behavioral reactions in fishes due to exposure to loud sounds (Hawkins et al., 2015; Popper & Hastings, 2009a; Popper et al., 2014). Repeated exposures of an individual to multiple sound-producing activities over a season, year, or life stage could cause reactions with costs that can accumulate over time to cause long-term consequences for the individual. These long-term consequences may affect the survivability of the individual, or if impacting enough individuals may have population-level effects, including alteration from migration paths, avoidance of important habitat, or even cessation of foraging or reproductive behavior (Hawkins et al., 2015). Conversely, some animals habituate to or become tolerant of repeated exposures over time, learning to ignore a stimulus that in the past has not accompanied any overt threat. In fact, Sivle et al. (2016) predicted that exposures to sonar at the maximum levels tested would only result in short-term disturbance and would not likely affect the overall population in sensitive fishes such as Atlantic herring (a species which does not occur in the MITT Study Area).

3.9.2.1.2 Impacts from Sonar and Other Transducers

The overall use of sonar and other transducers for training and testing would be similar to what is currently conducted (see Table 2.5-1 and Table 3.0-2 for details). Although individual activities may vary some from those previously analyzed, and some new systems using new technologies would be tested under Alternative 1 and 2, the overall determinations presented in the 2015 MITT Final EIS/OEIS remain valid.



Sonar and other transducers proposed for use are transient in most locations because activities that involve sonar and other transducers take place at different locations and many platforms are generally moving throughout the Study Area. A few activities involving sonar and other transducers occur in inshore waters (within bays and estuaries), including at pierside locations where they reoccur. Sonar and other transducers emit sound waves into the water to detect objects, safely navigate, and communicate. General categories and characteristics of these systems and the number of hours these sonars would be operated are described in Section 3.0.4.1.1 (Sonar and Other Transducers). The activities analyzed in this SEIS/OEIS that use sonar and other transducers are described in Appendix A (Training and Testing Activities Descriptions).

As described under Section 3.9.2.1.1.1 (Injury – Injury due to Sonar and Other Transducers), direct injury from sonar and other transducers is highly unlikely because injury has not been documented in fish exposed to sonar (Halvorsen et al., 2012c; Halvorsen et al., 2013; Popper et al., 2007) and therefore is not considered further in this analysis.

Fishes are not equally sensitive to noise at all frequencies. Fishes must first be able to hear a sound in order to be affected by it. As discussed in Section 3.9.1.1 (Hearing and Vocalization), many marine fish species tested to date hear primarily below 1 kHz. For the purposes of this analysis, fish species were grouped into one of four fish hearing groups based on either their known hearing ranges (i.e., audiograms) or physiological features that may be linked to overall hearing capabilities (i.e., swim bladder with connection to, or in close proximity to, the inner ear). Figure 3.9-1 provides a general summary of hearing threshold data from available literature (e.g., Casper & Mann, 2006; Deng et al., 2013; Kéver et al., 2014; Mann et al., 2001; Ramcharitar et al., 2006) to demonstrate the maximum potential range of frequency detection for each hearing group.

Due to data limitations, these estimated hearing ranges may be overly conservative in that they may extend beyond what some species within a given fish hearing group may actually detect. For example, although most sharks are sensitive to lower frequencies, well below 1 kHz, the bull shark has been tested and can detect frequencies up to 1.5 kHz (Kritzler & Wood, 1961; Myrberg, 2001) and therefore represents the uppermost known limit of frequency detection for this hearing group. These upper bounds of each fish hearing groups' frequency range are outside of the range of best sensitivity for the majority of fishes within that group. As a result, fishes within each group would only be able to detect those upper frequencies at close distances to the source, and from sources with relatively high source levels.

Figure 3.9-1 is not intended as a composite audiogram but rather displays the basic overlap in potential frequency content for each hearing group with Navy defined sonar classes (i.e., low-, mid-, high- and very high-frequency) as discussed under Section 3.0.4.1.1 (Sonar and Other Transducers – Classification of Sonar and Other Transducers).

Notes: Thin blue lines represent the estimated minimum and maximum range of frequency detection for each group. All hearing groups are assumed to hear down to 0.01 kHz regardless of available data. Thicker portions of each blue line represent the estimated minimum and maximum range of best sensitivity for that group. Currently, no data are available to estimate the range of best sensitivity for fishes without a swim bladder. Although each sonar class is represented graphically by the horizontal black, grey and brown bars, not all sources within each class would operate at all the displayed frequencies. Example mid-frequency sources are provided to further demonstrate this. kHz = kilohertz, MF1 = 3.5 kHz, MF4 = 4 kHz, MF5 = 8 kHz.

Figure 3.9-1: Fish Hearing Group and Navy Sonar Bin Frequency Ranges

Systems within the low-frequency sonar class present the greatest potential for overlap with fish hearing. Some mid-frequency sonars and other transducers may also overlap some species' hearing ranges, but to a lesser extent than low-frequency sonars. For example, the only hearing groups that have the potential to be able to detect mid-frequency sources within bins MF1, MF4, and MF5 are fishes with a swim bladder involved in hearing and with high-frequency hearing. It is anticipated that most fishes would not hear or be affected by mid-frequency Navy sonars or other transducers with operating frequencies greater than about 1–4 kHz. Only a few fish species (i.e., fish with a swim bladder and high-frequency hearing specializations) can detect and therefore be potentially affected by high- and very high-frequency sonars and other transducers.

The most probable impacts from exposure to sonar and other transducers are TTS (for more detail see Section 3.9.2.1.1.2, Hearing Loss), masking (for more detail see Section 3.9.2.1.1.3, Masking), physiological stress (for more detail see Section 3.9.2.1.1.4, Physiological Stress), and behavioral

reactions (for more detail see Section 3.9.2.1.1.5, Behavioral Reactions). Analysis of these effects are provided below.

3.9.2.1.2.1 Methods for Analyzing Impacts from Sonar and Other Transducers

The Navy performed a quantitative analysis to estimate the range to TTS for fishes exposed to sonar and other transducers used during Navy training and testing activities. Inputs to the quantitative analysis included sound propagation modeling in the Navy Acoustic Effects Model to the sound exposure criteria and thresholds presented below to predict ranges to effects. Although ranges to effect are predicted, density data for fish species within the Study Area are not available; therefore, it is not possible to estimate the total number of individuals that may be affected by sound produced by sonar and other transducers.

Criteria and thresholds to estimate impacts from sonar and other transducers are presented below in Table 3.9-3. Thresholds for hearing loss are typically reported in cumulative sound exposure level so as to account for the duration of the exposure. Therefore, thresholds reported in the *ANSI Sound Exposure Guideline* technical report (Popper et al., 2014) that were presented in other metrics were converted to sound exposure level based on the signal duration reported in the original studies (see Halvorsen et al., 2012c; Halvorsen et al., 2013; Kane et al., 2010; Popper et al., 2007). General research findings from these studies can be reviewed in Section 3.9.2.1.1.2 (Hearing Loss).

Table 3.9-3: Sound Exposure Criteria for TTS from Sonar

Fish Hearing Group	*TTS from Low-Frequency Sonar (SEL_{cum})*	*TTS from Mid-Frequency Sonar (SEL_{cum})*
Fishes without a swim bladder	NC	NC
Fishes with a swim bladder not involved in hearing	> 210	NC
Fishes with a swim bladder involved in hearing	210	220
Fishes with a swim bladder and high-frequency hearing	210	220

Notes: TTS = Temporary Threshold Shift, SEL_{cum} = Cumulative sound exposure level (decibel referenced to 1 micropascal squared seconds [dB re 1 μPa^2-s]), NC = effects from exposure to sonar is considered to be unlikely, therefore no criteria are reported, ">" indicates that the given effect would occur above the reported threshold.

For mid-frequency sonars, fishes with a swim bladder involved in hearing have shown signs of hearing loss because of mid-frequency sonar exposure at a maximum received sound pressure level of 210 dB re 1 µPa for a total duration of 15 seconds. To account for the total duration of the exposure, the threshold for TTS is a cumulative sound exposure level of 220 dB re 1 μPa^2-s (Halvorsen et al., 2012c; Kane et al., 2010). The same threshold is used for fishes with a swim bladder and high-frequency hearing as a conservative measure, although fishes in this hearing group have not been tested for the same impact. TTS has not been observed in fishes with a swim bladder that is not involved in hearing exposed to mid-frequency sonar. Fishes within this hearing group do not sense pressure well and typically cannot hear at frequencies above 1 kHz (Halvorsen et al., 2012c; Popper et al., 2014). Therefore, no criteria were proposed for fishes with a swim bladder that is not involved in hearing from exposure to mid-frequency sonars, as it is considered unlikely for TTS to occur. Fishes without a swim bladder are

even less susceptible to noise exposure; therefore, TTS is unlikely to occur, and no criteria are proposed for this group either.

For low-frequency sonar, as described in Section 3.9.2.1.1.2 (Hearing Loss), exposure of fishes with a swim bladder has resulted in TTS (Halvorsen et al., 2013; Kane et al., 2010; Popper et al., 2007). Specifically, fishes with a swim bladder not involved in hearing showed signs of hearing loss after exposure to a maximum received sound pressure level of 193 dB re 1 µPa for 324 and 648 seconds (cumulative sound exposure level of 218 and 220 dB re 1 μPa^2-s, respectively) (Kane et al., 2010; Popper et al., 2007). In addition, exposure of fishes with a swim bladder involved in hearing to low-frequency sonar at a sound pressure level of 195 dB re 1 µPa for 324 seconds (cumulative sound exposure level of 215 dB re 1 μPa^2-s) resulted in TTS (Halvorsen et al., 2013). Although the results were variable, it can be assumed that TTS may occur in fishes within the same hearing groups at similar exposure levels. As a conservative measure, the threshold for TTS from exposure to low-frequency sonar for all fish hearing groups with a swim bladder was rounded down to a cumulative sound exposure level of 210 dB re 1 μPa^2-s.

Criteria for high- and very-high-frequency sonar were not available in the *ANSI Sound Exposure Guideline* technical report (Popper et al., 2014); however, only species with a swim bladder involved in hearing and with high-frequency specializations, such as shad, could potentially be affected. The majority of fish species within the Study Area are unlikely to be able to detect these sounds. There is little data available on hearing loss from exposure of fishes to these high-frequency sonars. Due to the lack of available data, and as a conservative measure, effects to these hearing groups from high-frequency sonars would utilize the lowest threshold available for other hearing groups (a cumulative sound exposure level of 210 dB re 1 μPa^2-s), but effects would largely be analyzed qualitatively.

3.9.2.1.2.2 Impact Ranges for Sonar and Other Transducers

The following section provides ranges to specific effects from sonar and other transducers. Ranges are calculated using criteria from Table 3.9-4 and the Navy Acoustic Effects Model. Only ranges to TTS were predicted based on available data. Sonar durations of 1, 30, 60 and 120 seconds were used to calculate the ranges below. However, despite the variation in exposure duration, ranges were almost identical across these durations and therefore were combined and summarized by bin in the table below. General source levels, durations, and other characteristics of these systems are described in Section 3.0.4.1.1 (Sonar and Other Transducers).

Table 3.9-4: Ranges to Temporary Threshold Shift from Four Representative Sonar Bins

Fish Hearing Group	*Range to Effects (meters)*			
	Sonar Bin LF4 Low-frequency	*Sonar Bin MF1 Hull-mounted surface ship sonars (e.g., AN/SQS-53C and AN/SQS-61)*	*Sonar Bin MF4 Helicopter-deployed dipping sonars (e.g., AN/AQS-22)*	*Sonar Bin MF5 Active acoustic sonobuoys (e.g., DICASS)*
Fishes without a swim bladder	NR	NR	NR	NR
Fishes with a swim bladder not involved in hearing	0	NR	NR	NR
Fishes with a swim bladder involved in hearing	0	7 (5–10)	0	0
Fishes with a swim bladder and high-frequency hearing	0	7 (5–10)	0	0

Notes: Ranges to TTS represent modeled predictions in different areas and seasons within the Study Area. The average range to TTS is provided as well as the minimum to the maximum range to TTS in parenthesis. Where only one number is provided the average, minimum, and maximum ranges to TTS are the same.
LF = low-frequency, MF = mid-frequency, NR = no criteria are available and therefore no range to effects are estimated.

3.9.2.1.2.3 Impacts from Sonar and Other Transducers Under Alternative 1

Sonar and other transducers emit sound waves into the water to detect objects, safely navigate, and communicate. Use of sonar and other transducers would typically be transient and temporary. General categories and characteristics of sonar systems and the number of hours these sonars would be operated during training and testing activities under Alternative 1 are described in Section 3.0.4.1.1 (Sonar and Other Transducers). Activities using sonars and other transducers would be conducted as described in Chapter 2 (Description of Proposed Action and Alternatives) and Appendix A (Training and Testing Activities Descriptions).

Under Alternative 1, training and testing activities including low-frequency sonars within most marine species hearing range (<2 kHz) would take place throughout the Study Area. Unit-level training and major training exercises would fluctuate each year to account for the natural variation of training cycles and deployment schedules. Some unit-level training would be conducted using synthetic means (e.g., simulators) or would be completed through other training exercises. Low-frequency sources are operated more frequently during testing activities than during training activities. Therefore, although the general impacts from sonar and other transducers during testing would be similar in severity to those described during training, there may be more impacts during testing activities as all marine fishes can detect low-frequency sources.

Only a few species of shad within the Clupeidae family, subfamily Alosinae, are known to be able to detect high-frequency sonar and other transducers (greater than 10 kHz) and are considered a part of the fish hearing group for species with a swim bladder that have high-frequency hearing. However, these species are not present in the MITT Study Area. Other marine fishes would probably not detect

these sounds and therefore would not experience masking, physiological stress, or behavioral disturbance from exposure to high or very high-frequency sonar and other transducers.

Most marine fish species are not expected to detect sounds in the mid-frequency range (above a few kHz) of most operational sonars. The fish species that are known to detect mid-frequencies (i.e., those with swim bladders including some sciaenids [drum], most clupeids [herring, shad], and potentially deep-water fish such as myctophids [lanternfish]) do not have their best sensitivities in the range of the operational sonars (see Figure 3.9-1). Thus, fishes may only detect the most powerful systems, such as hull-mounted sonar, within a few kilometers; and most other, less powerful mid-frequency sonar systems, for a kilometer or less. Fishes with a swim bladder involved in hearing and with high-frequency hearing are more susceptible to hearing loss due to exposure to mid-frequency sonars. However, as shown in Table 3.9-4, the maximum estimated range to TTS for these fish hearing groups is equal to or less than 10 m for only the most powerful sonar bins. Fishes within these hearing groups would have to be very close to the source and the source levels would have to be relatively high in order to experience this effect.

Most mid-frequency active sonars used in the Study Area would not have the potential to substantially mask key environmental sounds or produce sustained physiological stress or behavioral reactions due to the limited time of exposure due to the moving sound sources and variable duty cycles. However, it is important to note that some mid-frequency sonars have a high duty cycle or are operated continuously. This may increase the risk of masking but only for important biological sounds that overlap with the frequency of the sonar being operated. Furthermore, although some species may be able to produce sound at higher frequencies (greater than 1 kHz), vocal marine fishes, such as sciaenids, largely communicate below the range of mid-frequency levels used by most sonars. Any such effects would be temporary and infrequent as a vessel operating mid-frequency sonar transits an area. As such, mid-frequency sonar use is unlikely to impact individuals. Long-term consequences for fish populations due to exposure to mid-frequency sonar and other transducers are not expected.

All marine fish species can likely detect low-frequency sonars and other transducers. However, low-frequency active sonar use is rare and most low-frequency active operations are typically conducted in deeper, offshore areas. The majority of fish species, including those that are the most highly vocal, exist on the continental shelf and within nearshore, estuarine areas. However, some species may still be present in areas where low-frequency sonar and other transducers are used, including some coastal areas. Most low-frequency sonar sources do not have a high enough source level to cause TTS, as shown in Table 3.9-4. Although highly unlikely, if TTS did occur, it may reduce the detection of biologically significant sounds but would likely recover within a few minutes to days.

The majority of fish species exposed to sonar and other transducers within near (tens of meters) to far (thousands of meters) distances of the source would be more likely to experience; mild physiological stress; brief periods of masking; behavioral reactions such as startle or avoidance responses, although risk would be low even close to the source; or no reaction. However, based on the information provided in the *ANSI Sound Exposure Guideline* technical report (Popper et al., 2014), the relative risk of these effects at any distance are expected to be low. Due to the transient nature of most sonar operations, overall effects would be localized and infrequent, only lasting a few seconds or minutes. Based on the low level and short duration of potential exposure to low-frequency sonar and other transducers, long-term consequences for fish populations are not expected.

As discussed previously in Section 3.9.1.1 (Hearing and Vocalization) and as shown in Figure 3.9-1, all ESA-listed fish species that occur in the Study Area are capable of detecting sound produced by low-frequency sonars and other transducers. However, scalloped hammerhead sharks, giant manta rays and oceanic whitetip sharks do not have a swim bladder and cannot detect frequencies above 2 kHz therefore impacts from mid-, high- or very high-frequency sonar and other transducers are not expected for any ESA-listed species. The Indo-West Pacific Distinct Population Segment of scalloped hammerhead could occur in nearshore waters, such as bays and estuaries, but is also known to occur in offshore portions of the Study Area. The giant manta ray and oceanic whitetip shark would most likely be exposed to low-frequency sonar in offshore areas throughout the Study Area.

Impacts on ESA-listed fishes, if they occur, would be similar to impacts on fishes in general. As described above, most low-frequency sonar sources do not have a high enough source level to cause TTS, and TTS would not be anticipated in fishes without a swim bladder. Although some shark species have shown attraction to irregularly pulsed low-frequency sounds (below several hundred Hz), they are not known to be attracted to continuous signals or higher frequencies that they presumably cannot hear (Casper & Mann, 2006; Casper & Mann, 2009; Casper et al., 2012a). Due to the short-term, infrequent, and localized nature of these activities, ESA-listed fishes are unlikely to be exposed multiple times within a short period. In addition, physiological and behavioral reactions would be expected to be brief (e.g., seconds to minutes) and infrequent based on the low probability of co-occurrence between training activities and these species. Although individuals may be impacted, long-term consequences for populations would not be expected.

Pursuant to the ESA, the use of sonar and other transducers during training and testing activities, as described under Alternative 1, may affect ESA-listed Indo-West Pacific Distinct Population Segment scalloped hammerhead sharks, oceanic whitetip sharks and giant manta rays.

3.9.2.1.2.4 Impacts from Sonar and Other Transducers Under Alternative 2 (Preferred Alternative)

Sonar and other transducers emit sound waves into the water to detect objects, safely navigate, and communicate. Use of sonar and other transducers would typically be transient and temporary. General categories and characteristics of sonar systems and the number of hours these sonars would be operated during training and testing activities under Alternative 2 are described in Section 3.0.4.1.1 (Sonar and Other Transducers). Activities using sonars and other transducers would be conducted as described in Chapter 2 (Description of Proposed Action and Alternatives) and Appendix A (Training and Testing Activities Descriptions).

Under Alternative 2, training and testing activities could occur throughout the Study Area. Training activities include the same type and tempo of training activities as Alternative 1 but also considers additional Fleet exercises (e.g., Valiant Shield type event) every year. Alternative 2 reflects the maximum number of training events that could occur within a given year, and assumes that the maximum number of Fleet exercises would occur every year. However, the types and tempo of testing activities would be the same as those conducted under Alternative 1.

Compared to training and testing activities that use sonar and other transducers that were previously analyzed in the 2015 MITT Final EIS/OEIS under Alternative 2, some training and testing activities would increase, decrease, or stay the same from those currently conducted (see Table 2.5-1 and Table 2.5-2 for details).

Impacts on fishes due to sonar and other transducers are expected to be limited to minor behavioral responses, short-term physiological stress, and brief periods of masking (seconds to minutes at most) for individuals; long-term consequences for individuals and therefore populations would not be expected. Predicted impacts on ESA-listed fish species would not be discernible from those described above in Section 3.9.2.1.2.3 (Impacts from Sonar and Other Transducers under Alternative 1).

Pursuant to the ESA, the use of sonar and other transducers during training and testing activities, as described under Alternative 2, may affect ESA-listed Indo-West Pacific Distinct Population Segment scalloped hammerhead sharks, oceanic whitetip sharks and giant manta rays. The Navy is consulting with NMFS as required by Section 7(a)(2) of the ESA.

3.9.2.1.2.5 Impacts from Sonar and Other Transducers Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Acoustic stressors as listed above would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer sonar and other transducers within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for acoustic impacts on individual fishes, but would not measurably improve the status of fish populations or subpopulations, including those listed under ESA and those federally managed under the MSA.

3.9.2.1.3 Impacts from Vessel Noise

Fishes may be exposed to noise from vessel movement. A detailed description of the acoustic characteristics and typical sound levels of vessel noise are in Section 3.0.4.1.2 (Vessel Noise). Vessel movements involve transits to and from ports to various locations within the Study Area, including commercial ship traffic as well as recreational vessels in addition to U.S. Navy vessels. Many ongoing and proposed training and testing activities within the Study Area involve maneuvers by various types of surface ships, boats, and submarines (collectively referred to as vessels). Activities may vary from those previously analyzed in the 2015 MITT Final EIS/OEIS, but the overall determinations presented remain valid. Increases and decreases shown in Table 2.5-1 and Table 2.5-2 for proposed activities under Alternative 1 and 2 do not appreciably change the impact conclusions presented in the 2015 MITT Final EIS/OEIS.

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Acoustic stressors, as described above, would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in less vessel noise within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for acoustic impacts on individual fishes, but would not measurably improve the status of fish

populations or subpopulations, including those listed under ESA and those federally managed under the MSA.

Pursuant to the ESA, sound produced by vessel movement during training and testing activities, as described under Alternative 1 and Alternative 2, may affect ESA-listed Indo-West Pacific Distinct Population Segment scalloped hammerhead sharks, oceanic whitetip sharks and giant manta rays. The Navy is consulting with NMFS regarding Alternative 2 as required by Section 7(a)(2) of the ESA.

3.9.2.1.4 Impacts from Aircraft Noise

Fishes that occur near or at the water's surface may be exposed to aircraft noise, although this is considered to be unlikely. Fixed, rotary-wing, and tilt-rotor aircraft are used during a variety of training and testing activities throughout the Study Area. Tilt-rotor impacts would be similar to fixed-wing or rotary-wing (i.e., helicopter) impacts depending which mode the aircraft is in. Most of these sounds would be concentrated around airbases and fixed ranges within the range complex. Aircraft noise could also occur in the waters immediately surrounding aircraft carriers at sea during takeoff and landing. Aircraft produce extensive airborne noise from either turbofan or turbojet engines. An infrequent type of aircraft noise is the sonic boom, produced when the aircraft exceeds the speed of sound. Rotary-wing aircraft (helicopters) produce low-frequency sound and vibration (Pepper et al., 2003). A detailed description of aircraft noise as a stressor is in Section 3.0.4.1.3 (Aircraft Noise).

Activities may vary from those previously analyzed in the 2015 MITT Final EIS/OEIS. The analysis of impacts from aircraft noise in this Supplemental EIS/OEIS supplants the 2015 MITT Final EIS/OEIS for fishes, and changes estimated impacts for some species since the 2015 MITT Final EIS/OEIS.

3.9.2.1.4.1 Methods for Analyzing Impacts from Aircraft Noise

The amount of sound entering the ocean from aircraft would be very limited in duration, sound level, and affected area. Due to the low level of sound that could enter the water from aircraft activities, hearing loss is not further considered as a potential effect. Potential impacts considered are masking of other biologically relevant sounds, physiological stress, and changes in behavior. Reactions by fishes to these specific stressors have not been recorded; however, fishes would be expected to react to aircraft noise as they would react to other transient sounds (e.g., sonar or vessel noise).

For this analysis, the Navy assumes that some fish at or near the water surface may exhibit startle reactions to certain aircraft noise if aircraft altitude is low. This could mean a hovering helicopter, for which the sight of the aircraft and water turbulence could also cause a response, or a low-flying or super-sonic aircraft generating enough noise to be briefly detectable underwater or at the air-water interface. Because any fixed-wing aircraft noise would be brief, the risk of masking any sounds relevant to fishes is very low. The *ANSI Sound Exposure Guidelines* for fishes did not consider this acoustic stressor (Popper et al., 2014).

3.9.2.1.4.2 Impacts from Aircraft Noise Under Alternative 1

Fishes may be exposed to aircraft-generated noise throughout the Study Area. Characteristics of aircraft noise and the number of training and testing events that include aircraft under Alternative 1 are shown in Section 3.0.4.1.3 (Aircraft Noise). Activities with aircraft would be conducted as described in Chapter 2 (Description of Proposed Action and Alternatives) and Appendix A (Training and Testing Activities Descriptions). Aircraft training and testing activities would usually occur adjacent to Navy airfields, installations, and in special use airspace within the Study Area and transit corridor.

Under Alternative 1, activities may vary from those previously analyzed in the 2015 MITT Final EIS/OEIS. Increases and decreases shown in Table 2.5-1 and Table 2.5-2 for proposed activities under Alternative 1 and 2.

In most cases, exposure of fishes to fixed-wing aircraft presence and noise would be brief as the aircraft quickly passes overhead. Fishes would have to be at or near the surface at the time of an overflight to be exposed to appreciable sound levels. Due to the low sound levels in water, it is unlikely that fishes would respond to most fixed-wing aircraft or transiting helicopters. Because most overflight exposure would be brief and aircraft noise would be at low received levels, only startle reactions, if any, are expected in response to low altitude flights. Similarly, the brief duration of most overflight exposures would limit any potential for masking of relevant sounds.

Daytime and nighttime activities involving helicopters may occur for extended periods of time, up to a couple of hours in some areas. During these activities, helicopters would typically transit throughout an area but could also hover over the water. Longer event durations and periods of time where helicopters hover may increase the potential for behavioral reactions, startle reactions, masking, and physiological stress. Low-altitude flights of helicopters during some activities, which often occur under 100 feet (ft.) altitude, may elicit a stronger startle response due to the proximity of a helicopter to the water; the slower airspeed and longer exposure duration; and the downdraft created by a helicopter's rotor.

If fish were to respond to aircraft noise, only short-term behavioral or physiological reactions (e.g., avoidance and increased heart rate) would be expected. Therefore, long-term consequences for individuals would be unlikely and long-term consequences for populations are not expected.

All ESA-listed species that occur in the Study Area are likely capable of detecting aircraft noise as discussed previously in Section 3.9.1.1 (Hearing and Vocalization) and could be exposed to aircraft noise throughout the Study Area. However, due to the small area within which sound could potentially enter the water and the extremely brief window the sound could be present, exposures of fishes to aircraft noise would be extremely rare, and in the event that they did occur, would be very brief (seconds).

Pursuant to the ESA, sound produced by aircraft movement during training and testing activities, as described under Alternative 1, may affect ESA-listed Indo-West Pacific Distinct Population Segment scalloped hammerhead sharks, oceanic whitetip sharks and giant manta rays.

3.9.2.1.4.3 Impacts from Aircraft Noise Under Alternative 2 (Preferred Alternative)

Characteristics of aircraft noise and the number of training and testing events that include aircraft under Alternative 2 are shown in Section 3.0.4.1.3 (Aircraft Noise). Activities with aircraft would be conducted as described in Chapter 2 (Description of Proposed Action and Alternatives) and Appendix A (Training and Testing Activities Descriptions). Aircraft training and testing activities would usually occur adjacent to Navy airfields, installations, and in special use airspace within the Study Area and transit corridor.

Under Alternative 2, activities may vary from those previously analyzed in the 2015 MITT Final EIS/OEIS. Increases and decreases shown in Table 2.5-1 and Table 2.5-2 for proposed activities under Alternative 1 and 2.

Activities under Alternative 2 include a minor increase in the number of events that involve aircraft as compared to Alternative 1; however, the training locations, aircraft, and general types of predicted impacts would not be discernible from those described above in Section 3.9.2.1.4.2 (Impacts from Aircraft Noise Under Alternative 1).

Pursuant to the ESA, sound produced by aircraft movement during training and testing activities, as described under Alternative 2, may affect ESA-listed Indo-West Pacific Distinct Population Segment scalloped hammerhead sharks, oceanic whitetip sharks and giant manta rays. The Navy is consulting with NMFS as required by Section 7(a)(2) of the ESA.

3.9.2.1.4.4 Impacts from Aircraft Noise Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Acoustic stressors, as described above, would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in less acoustic stressors within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for acoustic impacts on individual fishes, but would not measurably improve the status of fish populations or subpopulations, including those listed under ESA and those federally managed under the MSA.

3.9.2.1.5 Impacts from Weapon Noise

Fishes may be exposed to sounds caused by the firing of weapons, objects in flight, and impact of non-explosive munitions on the water's surface, which are described in Section 3.0.4.1.4 (Weapon Noise). In general, these are impulsive sounds (such as those discussed under Section 3.0.4.2, Explosive Stressors) generated in close vicinity to or at the water surface, with the exception of items that are launched underwater. The firing of a weapon may have several components of associated noise. Firing of guns could include sound generated in air by firing a gun (muzzle blast) and a crack sound due to a low amplitude shock wave generated by a supersonic projectile flying through the air. Most in-air sound would be reflected at the air-water interface. Underwater sounds would be strongest just below the surface and directly under the firing point. Any sound that enters the water only does so within a narrow cone below the firing point or path of the projectile. Vibration from the blast propagating through a ship's hull, the sound generated by the impact of an object with the water surface, and the sound generated by launching an object underwater are other sources of impulsive sound in the water. Sound due to missile and target launches is typically at a maximum at initiation of the booster rocket and rapidly fades as the missile or target travels downrange. Due to the transient nature of most activities that produce weapon noise, overall effects would be localized and infrequent, only lasting a few seconds or minutes. Reactions by fishes to these specific stressors have not been recorded however, fishes would be expected to react to weapon noise as they would react to other transient sounds (e.g., sonar or vessel noise).

Activities may vary from those previously analyzed in the 2015 MITT Final EIS/OEIS, but the overall determinations presented remain valid. Increases and decreases shown in Table 2.5-1 and Table 2.5-2 for activities proposed under Alternative 1 and 2 do not appreciably change the impact conclusions presented in the 2015 MITT Final EIS/OEIS.

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Acoustic stressors, as described above, would not be introduced into the marine environment. Therefore, existing

environmental conditions would either remain unchanged or would improve after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in less acoustic stressors within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for acoustic impacts on individual fishes, but would not measurably improve the status of fish populations or subpopulations, including those listed under ESA and those federally managed under the MSA.

Pursuant to the ESA, sound produced by weapon noise during training and testing activities, as described under Alternative 1 and Alternative 2, may affect ESA-listed Indo-West Pacific Distinct Population Segment scalloped hammerhead sharks, oceanic whitetip sharks and giant manta rays. The Navy is consulting with NMFS regarding Alternative 2 as required by Section 7(a)(2) of the ESA.

3.9.2.2 Explosive Stressors

Explosions in the water or near the water surface can introduce loud, impulsive, broadband sounds into the marine environment. However, unlike other acoustic stressors, explosives release energy at a high rate producing a shock wave that can be injurious and even deadly. Therefore, explosive impacts on fishes are discussed separately from other acoustic stressors, even though the analysis of explosive impacts will rely on data for fish impacts due to impulsive sound exposure where appropriate.

Explosives are usually described by their net explosive weight, which accounts for the weight and type of explosive material. Additional explanation of the acoustic and explosive terms and sound energy concepts used in this section is found in Appendix H (Acoustic and Explosive Concepts).

This section begins with a summary of relevant data regarding explosive impacts on fishes in Section 3.9.2.2.1 (Background). The ways in which an explosive exposure could result in immediate effects or lead to long-term consequences for an animal are explained in Section 3.0.4.7 (Conceptual Framework for Assessing Effects from Acoustic and Explosive Activities), and this section follows that framework.

Although air guns and pile driving are not used during MITT training and testing activities, the analysis of some explosive impacts will in part rely on data from fishes exposed to impulsive sources where appropriate. Impulsive sources are further discussed below when applicable data are available for comparison purposes. In addition, there are limited studies of fish responses to weapon noise. For the purposes of this analysis, studies of the effects from air guns, pile driving, and explosives are used to inform fish responses to other impulsive sources (i.e., weapon noise).

Due to the availability of new literature, adjusted sound exposure criteria, and new acoustic effects modeling, the analysis provided in Section 3.9.2.2.2 (Impacts from Explosives) of this SEIS/OEIS supplants the 2015 MITT Final EIS/OEIS for fishes.

3.9.2.2.1 Background

The effects of explosions on fishes have been studied and reviewed by numerous authors (Keevin & Hempen, 1997; O'Keeffe, 1984; O'Keeffe & Young, 1984; Popper et al., 2014). A summary of the literature related to each type of effect forms the basis for analyzing the potential effects from Navy activities. The sections below include a survey and synthesis of best-available science published in peer-reviewed journals, technical reports, and other scientific sources pertinent to impacts on fishes

potentially resulting from Navy training and testing activities. Fishes could be exposed to a range of impacts depending on the explosive source and context of the exposure. In addition to acoustic impacts including temporary or permanent hearing loss, auditory masking, physiological stress, or changes in behavior, potential impacts from an explosive exposure can include non-lethal injury and mortality.

3.9.2.2.1.1 Injury

Injury refers to the direct effects on the tissues or organs of a fish. The blast wave from an in-water explosion is lethal to fishes at close range, causing massive organ and tissue damage (Keevin & Hempen, 1997). At greater distance from the detonation point, the extent of mortality or injury depends on a number of factors, including fish size, body shape, depth, physical condition of the fish, and perhaps most importantly, the presence of a swim bladder (Keevin & Hempen, 1997; Wright, 1982; Yelverton et al., 1975; Yelverton & Richmond, 1981). At the same distance from the source, larger fishes are generally less susceptible to death or injury, elongated forms that are round in cross-section are less at risk than deep-bodied forms, and fishes oriented sideways to the blast suffer the greatest impact (Edds-Walton & Finneran, 2006; O'Keeffe, 1984; O'Keeffe & Young, 1984; Wiley et al., 1981; Yelverton et al., 1975). Species with a swim bladder are much more susceptible to blast injury from explosives than fishes without them (Gaspin, 1975; Gaspin et al., 1976; Goertner et al., 1994).

If a fish is close to an explosive detonation, the exposure to rapidly changing high pressure levels can cause barotrauma. Barotrauma is injury due to a sudden difference in pressure between an air space inside the body and the surrounding water and tissues. Rapid compression followed by rapid expansion of airspaces, such as the swim bladder, can damage surrounding tissues and result in the rupture of the airspace itself. The swim bladder is the primary site of damage from explosives (Wright, 1982; Yelverton et al., 1975). Gas-filled swim bladders resonate at different frequencies than surrounding tissue and can be torn by rapid oscillation between high- and low-pressure waves (Goertner, 1978). Swim bladders are a characteristic of most bony fishes with the notable exception of flatfishes (e.g., halibut). Sharks and rays are examples of fishes without a swim bladder. Small airspaces, such as micro-bubbles that may be present in gill structures, could also be susceptible to oscillation when exposed to the rapid pressure increases caused by an explosion. This may have caused the bleeding observed on gill structures of some fish exposed to explosions (Goertner et al., 1994). Sudden very high pressures can also cause damage at tissue interfaces due to the way pressure waves travel differently through tissues with different densities. Rapidly oscillating pressure waves might rupture the kidney, liver, spleen, and sinus and cause venous hemorrhaging (Keevin & Hempen, 1997).

Several studies have exposed fish to explosives and examined various metrics in relation to injury susceptibility. Sverdrup (1994) exposed Atlantic salmon (1–1.5 kg [2–3 lb.]) in a laboratory setting to repeated shock pressures of around 2 megapascals (300 pounds per square inch [psi]) without any immediate or delayed mortality after a week. Hubbs and Rechnitzer (1952) showed that fish with swim bladders exposed to explosive shock fronts (the near-instantaneous rise to peak pressure) were more susceptible to injury when several feet below the water surface than near the bottom. When near the surface, the fish began to exhibit injuries around peak pressure exposures of 40 to 70 psi. However, near the bottom (all water depths were less than 100 ft.) fish exposed to pressures over twice as high exhibited no sign of injury. Yelverton et al. (1975) similarly found that peak pressure was not correlated to injury susceptibility; instead, injury susceptibility of swim bladder fish at shallow depths (10 ft. or less) was correlated to the metric of positive impulse (pascal seconds [Pa-s]), which takes into account both the positive peak pressure, the duration of the positive pressure exposure, and the fish mass, with smaller fish being more susceptible.

Gaspin et al. (1976) exposed multiple species of fish with a swim bladder, placed at varying depths, to explosive blasts of varying size and depth. Goertner (1978) and Wiley (1981) developed a swim bladder oscillation model, which showed that the severity of injury observed in those tests could be correlated to the extent of swim bladder expansion and contraction predicted to have been induced by exposure to the explosive blasts. Per this model, the degree of swim bladder oscillation is affected by ambient pressure (i.e., depth of fish), peak pressure of the explosive, duration of the pressure exposure, and exposure to surface rarefaction (negative pressure) waves. The maximum potential for injury is predicted to occur where the surface reflected rarefaction (negative) pressure wave arrives coincident with the moment of maximum compression of the swim bladder caused by exposure to the direct positive blast pressure wave, resulting in a subsequent maximum expansion of the swim bladder. Goertner (1978) and Wiley et al. (1981) found that their swim bladder oscillation model explained the injury data in the Yelverton et al. (1975) exposure study, and their impulse parameter was applicable only to fishes at shallow enough depths to experience less than one swim bladder oscillation before being exposed to the following surface rarefaction wave.

O'Keeffe (1984) provides calculations and contour plots that allow estimation of the range to potential effects of in-water explosions on fish possessing swim bladders using the damage prediction model developed by Goertner (1978). O'Keeffe's (1984) parameters include the charge weight, depth of burst, and the size and depth of the fish, but the estimated ranges do not take into account unique propagation environments that could reduce or increase the range to effect. The 10 percent mortality range shown below in Table 3.9-5 is the maximum horizontal range predicted by O'Keeffe (1984) for 10 percent of fish suffering injuries that are expected to not be survivable (e.g., damaged swim bladder or severe hemorrhaging). Fish at greater depths and near the surface are predicted to be less likely to be injured because geometries of the exposures would limit the amplitude of swim bladder oscillations. In addition, detonations at or near the surface (i.e., similar to most Navy activities that utilize bombs and missiles) would result in energy loss at the water air interface, resulting in lower overall ranges to effect than those predicted here.

In contrast to fish with swim bladders, fishes without swim bladders have been shown to be more resilient to explosives (Gaspin, 1975; Gaspin et al., 1976; Goertner et al., 1994). For example, some small (average 116 mm length; approximately 1 oz.) hogchokers (*Trinectes maculatus*) exposed less than 5 ft. from a 10 lb. pentolite charge immediately survived the exposure with slight to moderate injuries, and only a small number of fish were immediately killed; however, most of the fish at this close range did suffer moderate to severe injuries, typically of the gills or around the otolithic structures (Goertner et al., 1994).

Studies that have documented caged fishes killed during planned underwater explosions indicate that most fish that die do so within one to four hours, and almost all die within a day (Yelverton et al., 1975). Mortality in free-swimming (uncaged) fishes may be higher due to increased susceptibility to predation. Fitch and Young (1948) found that the type of free-swimming fish killed changed when blasting was repeated at the same location within 24 hours of previous blasting. They observed that most fish killed on the second day were scavengers, presumably attracted by the victims of the previous day's blasts.

Table 3.9-5: Range to 10 Percent Mortality from In-water Explosions for Fishes with a Swim Bladder

Weight of Pentolite (lb.) [NEW, lb.][1]	*Depth of Explosion (ft.) [m]*	*10% Mortality Maximum Range (ft.) [m]*		
		1 oz. Fish	*1 lb. Fish*	*30 lb. Fish*
10 [13]	10 [3]	530 [162]	315 [96]	165 [50]
	50 [15]	705 [214]	425 [130]	260 [79]
	200 [61]	905 [276]	505 [154]	290 [88]
100 [130]	10 [3]	985 [300]	600 [183]	330 [101]
	50 [15]	1,235 [376]	865 [264]	590 [180]
	200 [61]	1,340 [408]	1,225 [373]	725 [221]
1,000 [1,300]	10 [3]	1,465 [447]	1,130 [344]	630 [192]
	50 [15]	2,255 [687]	1,655 [504]	1,130 [344]
	200 [61]	2,870 [875]	2,390 [728]	1,555 [474]
10,000 [13,000]	10 [3]	2,490 [759]	1,920 [585]	1,155 [352]
	50 [15]	4,090 [1,247]	2,885 [879]	2,350 [716]
	200 [61]	5,555 [1,693]	4,153 [1,266]	3,090 [942]

[1] Explosive weights of pentolite converted to net explosive weight using the peak pressure parameters in Swisdak (1978).
Notes: ft. = feet, lb. = pounds, m = meters, NEW = net explosive weight, oz. = ounce
Source: Data from O'Keeffe (1984)

Fitch and Young (1948) also investigated whether a significant portion of fish killed would have sunk and not been observed at the surface. Comparisons of the numbers of fish observed dead at the surface and at the bottom in the same affected area after an explosion showed that fish found dead on the bottom comprised less than 10 percent of the total observed mortality. Gitschlag et al. (2000) conducted a more detailed study of both floating fishes and those that were sinking or lying on the bottom after explosive

removal of nine oil platforms in the northern Gulf of Mexico. Results were highly variable. They found that 3–87 percent (46 percent average) of the red snapper killed during a blast might float to the surface. Currents, winds, and predation by seabirds or other fishes may be some of the reasons that the magnitude of fish mortality may not have been accurately captured.

There have been few studies of the impact of underwater explosives on early life stages of fish (eggs, larvae, juveniles). Fitch and Young (1948) reported mortality of larval anchovies exposed to underwater blasts off California. Nix and Chapman (1985) found that anchovy and smelt larvae died following the detonation of buried charges. Similar to adult fishes, the presence of a swim bladder contributes to shock wave-induced internal damage in larval and juvenile fish (Settle et al., 2002). Explosive shock wave injury to internal organs of larval pinfish and spot exposed at shallow depths was documented by Settle et al. (2002) and Govoni et al. (2003; 2008) at impulse levels similar to those predicted by Yelverton et al. (1975) for very small fish. Settle et al. (2002) provide the lowest measured received level that injuries have been observed in larval fish. Researchers (Faulkner et al., 2006; Faulkner et al., 2008; Jensen, 2003) have suggested that egg mortality may be correlated with peak particle velocity exposure (i.e., the localized movement or shaking of water particles, as opposed to the velocity of the blast wave), although sufficient data from direct explosive exposures is not available (2003; 2008).

Rapid pressure changes could cause mechanical damage to sensitive ear structures due to differential movements of the otolithic structures. Bleeding near otolithic structures was the most commonly observed injury in non-swim bladder fish exposed to a close explosive charge (Goertner et al., 1994).

As summarized by the *ANSI Sound Exposure Guideline* technical report (Popper et al., 2014), exposure to explosive energy poses the greatest potential threat for injury and mortality in marine fishes. Fishes with a swim bladder are more susceptible to injury than fishes without a swim bladder. The susceptibility also probably varies with size and depth of both the detonation and the fish. Fish larvae or juvenile fish may be more susceptible to injury from exposure to explosives.

3.9.2.2.1.2 Hearing Loss

There are no direct measurements of hearing loss in fishes due to exposure to explosive sources. The sound resulting from an explosive detonation is considered an impulsive sound and shares important qualities (i.e., short duration and fast rise time) with other impulsive sounds such as those produced by air guns. PTS in fish has not been known to occur in species tested to date and any hearing loss in fish may be as temporary as the timeframe required to repair or replace the sensory cells that were damaged or destroyed (Popper et al., 2005; Popper et al., 2014; Smith et al., 2006).

As reviewed in the *ANSI Sound Exposure Guideline* technical report (Popper et al., 2014), fishes without a swim bladder, or fishes with a swim bladder not involved in hearing, would be less susceptible to hearing loss (i.e., TTS), even at higher level exposures. Fish with a swim bladder involved in hearing may be susceptible to TTS within very close ranges to an explosive. General research findings regarding TTS in fishes as well as findings specific to exposure to other impulsive sound sources are discussed in Section 3.9.2.1.1.2 (Hearing Loss).

3.9.2.2.1.3 Masking

Masking refers to the presence of a noise that interferes with a fish's ability to hear biologically important sounds, including those produced by prey, predators, or other fish in the same species (Myrberg, 1980; Popper et al., 2003). This can take place whenever the noise level heard by a fish exceeds the level of a biologically relevant sound. As discussed in Section 3.0.4.7 (Conceptual

Framework for Assessing Effects from Acoustic and Explosive Activities), masking only occurs in the presence of the masking noise and does not persist after the cessation of the noise. Masking may lead to a change in vocalizations or a change in behavior (e.g., cessation of foraging, leaving an area).

There are no direct observations of masking in fishes due to exposure to explosives. The *ANSI Sound Exposure Guideline* technical report (Popper et al., 2014) highlights a lack of data that exist for masking by explosives but suggests that the intermittent nature of explosions would result in very limited probability of any masking effects, and if masking were to occur it would only occur during the duration of the sound. General research findings regarding masking in fishes due to exposure to sound are discussed in detail in Section 3.9.2.1.1.3 (Masking). Potential masking from explosives is likely to be similar to masking studied for other impulsive sounds such as air guns.

3.9.2.2.1.4 Physiological Stress

Fishes naturally experience stress within their environment and as part of their life histories. The stress response is a suite of physiological changes that are meant to help an organism mitigate the impact of a stressor. However, if the magnitude and duration of the stress response is too great or too long, then it can have negative consequences to the organism (e.g., decreased immune function, decreased reproduction). Section 3.0.4.7 (Conceptual Framework for Assessing Effects from Acoustic and Explosive Activities) provides additional information on physiological stress and the framework used to analyze this potential impact.

Research on physiological stress in fishes due to exposure to explosive sources is limited. Sverdrup et al. (1994) studied levels of stress hormones in Atlantic salmon after exposure to multiple detonations in a laboratory setting. Increases in cortisol and adrenaline were observed following the exposure, with adrenaline values returning to within normal range within 24 hours. General research findings regarding physiological stress in fishes due to exposure to acoustic sources are discussed in detail in Section 3.9.2.1.1.4 (Physiological Stress). Generally, stress responses are more likely to occur in the presence of potentially threatening sound sources such as predator vocalizations or the sudden onset of impulsive signals. Stress responses may be brief (a few seconds to minutes) if the exposure is short or if fishes habituate or learn to tolerate the noise. It is assumed that any physiological response (e.g., hearing loss or injury) or significant behavioral response is also associated with a stress response.

3.9.2.2.1.5 Behavioral Reactions

As discussed in Section 3.0.4.7 (Conceptual Framework for Assessing Effects from Acoustic and Explosive Activities), any stimuli in the environment can cause a behavioral response in fishes, including sound and energy produced by explosions. Behavioral reactions of fishes to explosions have not been recorded. Behavioral reactions from explosive sounds are likely to be similar to reactions studied for other impulsive sounds such as those produced by air guns. Impulsive signals, particularly at close range, have a rapid rise time and higher instantaneous peak pressure than other signal types, making them more likely to cause startle or avoidance responses. General research findings regarding behavioral reactions from fishes due to exposure to impulsive sounds, such as those associated with explosions, are discussed in detail in Section 3.9.2.1.1.5 (Behavioral Reactions).

As summarized by the *ANSI Sound Exposure Guideline* technical report (Popper et al., 2014), species may react differently to the same sound source depending on a number of variables, such as the animal's life stage or behavioral state (e.g., feeding, mating). Without data that are more specific it is assumed that fishes with similar hearing capabilities react similarly to all impulsive sounds outside or within the zone for hearing loss and injury. Observations of fish reactions to large-scale air gun surveys are informative,

but not necessarily directly applicable to analyzing impacts from the short-term, intermittent use of all impulsive sources. Fish have a higher probability of reacting when closer to an impulsive sound source (within tens of meters), and a decreasing probability of reaction at increasing distances (Popper et al., 2014).

3.9.2.2.1.6 Long-Term Consequences

Long-term consequences to a population are determined by examining changes in the population growth rate. For additional information on the determination of long-term consequences, see Section 3.0.4.7 (Conceptual Framework for Assessing Effects from Acoustic and Explosive Activities). Physical effects from explosive sources that could lead to a reduction in the population growth rate include mortality or injury, which could remove animals from the reproductive pool, and temporary hearing impairment or chronic masking, which could affect navigation, foraging, predator avoidance, or communication. The long-term consequences due to individual behavioral reactions, masking, and short-term instances of physiological stress are especially difficult to predict because individual experience over time can create complex contingencies, especially for fish species that live for multiple seasons or years. For example, a lost reproductive opportunity could be a measurable cost to the individual; however, short-term costs may be recouped during the life of an otherwise healthy individual. These factors are taken into consideration when assessing risk of long-term consequences.

3.9.2.2.2 Impacts from Explosives

This section analyzes the impacts on fishes due to in-water and in-air explosives that would be used during Navy training and testing activities, synthesizing the background information presented above.

As discussed above, sound and energy from in-water explosions are capable of causing mortality, injury, temporary hearing loss, masking, physiological stress, or a behavioral response, depending on the level and duration of exposure. The death of an animal would eliminate future reproductive potential, which is considered in the analysis of potential long-term consequences to the population. Exposures that result in non-auditory injuries may limit an animal's ability to find food, communicate with other animals, or interpret the surrounding environment. Impairment of these abilities can decrease an individual's chance of survival or affect its ability to reproduce. Temporary threshold shift can also impair an animal's abilities, although the individual may recover quickly with little significant effect.

The overall use of explosives for training and testing activities would be similar to what is currently conducted and several new testing activities would occur (see Table 2.5-1 and Table 2.5-2 for details). Although individual activities may vary some from those previously analyzed, the overall determinations presented in the 2015 MITT Final EIS/OEIS remain valid, but have been improved upon under this SEIS/OEIS.

3.9.2.2.2.1 Methods for Analyzing Impacts from Explosives

The Navy performed a quantitative analysis to estimate ranges to effect for fishes exposed to underwater explosives during Navy training and testing activities. Inputs to the quantitative analysis included sound propagation modeling in the Navy Acoustic Effects Model to the sound exposure criteria and thresholds presented below. Density data for fish species within the Study Area are not currently available; therefore, it is not possible to estimate the total number of individuals that may be affected by explosive activities.

Criteria and Thresholds used to Estimate Impacts on Fishes from Explosives

Mortality and Injury from Explosives

Criteria and thresholds to estimate impacts from sound and energy produced by explosive activities are presented in Table 3.9-6. In order to estimate the longest range at which a fish may be killed or mortally injured, the Navy based the threshold for mortal injury on the lowest pressure that caused mortalities in the study by Hubbs and Rechnitzer (1952), consistent with the recommendation in the *ANSI Sound Exposure Guideline* technical report (Popper et al., 2014). As described in Section 3.9.2.2.1.1 (Injury), this threshold likely overestimates the potential for mortal injury. The potential for mortal injury has been shown to be correlated to fish size, depth, and geometry of exposure, which are not accounted for by using a peak pressure threshold. However, until fish mortality models are developed that can reasonably consider these factors across multiple environments, use of the peak pressure threshold allows for a conservative estimate of maximum impact ranges.

Due to the lack of detailed data for onset of injury in fishes exposed to explosives, thresholds from impact pile driving exposures (Halvorsen et al., 2011; Halvorsen et al., 2012a; Halvorsen et al., 2012b) were used as a proxy for the analysis in the Atlantic Fleet Training and Testing FEIS/OEIS (U.S. Department of the Navy, 2018). Upon re-evaluation, it was decided that pile driving thresholds are too conservative and not appropriate to use in the analysis of explosive effects on fishes. Therefore, injury criteria have been revised as follows.

Thresholds for the onset of injury from exposure to explosions are not currently available and recommendations in the *ANSI Sound Exposure Guideline* technical report (Popper et al., 2014) only provide qualitative criteria for consideration. Therefore, available data from existing explosive studies were reviewed to provide a conservative estimate for a threshold to the onset of injury (Gaspin, 1975; Gaspin et al., 1976; Hubbs & Rechnitzer, 1952; Settle et al., 2002; Yelverton et al., 1975).

It is important to note that some of the available literature is not peer-reviewed and may have some caveats to consider when reviewing the data (e.g., issues with controls, limited details on injuries observed, etc.) but this information may still provide a better understanding of where injurious effects would begin to occur specific to explosive activities. The lowest threshold at which injuries were observed in each study were recorded and compared for consideration in selecting criteria. As a conservative measure, the absolute lowest peak sound pressure level recorded that resulted in injury, observed in exposures of larval fishes to explosions (Settle et al., 2002), was selected to represent the threshold to injury.

The injury threshold is consistent across all fish regardless of hearing groups due to the lack of rigorous data for multiple species. As discussed throughout Section 3.9.2.2.1.1 (Injury), it is important to note that these thresholds may be overly conservative, as there is evidence that fishes exposed to higher thresholds than those in Table 3.9-6 have shown no signs of injury (depending on variables such as the weight of the fish, size of the explosion, and depth of the cage (Gaspin, 1975; Gaspin et al., 1976; Hubbs & Rechnitzer, 1952; Settle et al., 2002; Yelverton et al., 1975). It is likely that adult fishes and fishes without a swim bladder would be less susceptible to injury than more sensitive hearing groups (i.e., fishes with a swim bladder) and larval fish.

Table 3.9-6: Sound Exposure Criteria for Mortality and Injury from Explosives

Fish Hearing Group	*Onset of Mortality*	*Onset of Injury*
	SPL_{peak}	SPL_{peak}
Fishes without a swim bladder	229	220
Fishes with a swim bladder not involved in hearing	229	220
Fishes with a swim bladder involved in hearing	229	220
Fishes with a swim bladder and high-frequency hearing	229	220

Note: SP_{Lpeak} = Peak sound pressure level.

The number of fish killed by an in-water explosion would depend on the population density near the blast, as well as factors discussed throughout Section 3.9.2.2.1.1 (Injury) such as net explosive weight, depth of the explosion, and fish size. For example, if an explosion occurred in the middle of a dense school of fish, a large number of fish could be killed. However, the probability of this occurring is low, based on the patchy distribution of dense schooling fish. Stunning from pressure waves could also temporarily immobilize fish, making them more susceptible to predation.

Fragments produced by exploding munitions at or near the surface may present a high-speed strike hazard for an animal at or near the surface. In water, however, fragmentation velocities decrease rapidly due to drag (Swisdak & Montanaro, 1992). Because blast waves propagate efficiently through water, the range to injury from the blast wave would likely extend beyond the range of fragmentation risk.

Hearing Loss from Explosives

Criteria and thresholds to estimate TTS from sound produced by explosive activities are presented below in Table 3.9-7. Direct (measured) TTS data from explosives are not available. Criteria used to define TTS from explosives is derived from data on fishes exposed to seismic air gun signals (Popper et al., 2005) as summarized in the *ANSI Sound Exposure Guideline* technical report (Popper et al., 2014). TTS has not been documented in fishes without a swim bladder from exposure to other impulsive sources (pile driving and air guns). Although it is possible that fishes without a swim bladder could receive TTS from exposure to explosives, fishes without a swim bladder are typically less susceptible to hearing impairment than fishes with a swim bladder. If TTS occurs in fishes without a swim bladder, it would likely occur within the range of injury; therefore, no thresholds for TTS are proposed. General research findings regarding hearing loss in fishes as well as findings specific to exposure to other impulsive sound sources are discussed in Section 3.9.2.2.1.2 (Hearing Loss).

As discussed in Section 3.9.2.2.1.2 (Hearing Loss), exposure to sound produced from seismic air guns at a cumulative sound exposure level of 186 dB re 1 μPa^2-s has resulted in TTS in fishes with a swim bladder involved in hearing (Popper et al., 2005). TTS has not occurred in fishes with a swim bladder not involved in hearing and would likely occur above the given threshold in Table 3.9-7.

Table 3.9-7: Sound Exposure Criteria for Hearing Loss from Explosives

Fish Hearing Group	*TTS (SEL_{cum})*
Fishes without a swim bladder	NC
Fishes with a swim bladder not involved in hearing	> 186
Fishes with a swim bladder involved in hearing	186
Fishes with a swim bladder and high-frequency hearing	186

Notes: TTS = Temporary Threshold Shift, SEL_{cum} = Cumulative sound exposure level (decibel referenced to 1 micropascal squared seconds [dB re 1 µPa2-s]), NC = no criteria are reported, ">" indicates that the given effect would occur above the reported threshold.

3.9.2.2.2.2 Impact Ranges for Explosives

The following section provides estimated range to effects for fishes exposed to sound and energy produced by explosives. Ranges are calculated using criteria from Table 3.9-6 and Table 3.9-7 and the Navy Acoustic Effects Model. Fishes within these ranges would be predicted to receive the associated effect. Ranges may vary greatly depending on factors such as the cluster size, location, depth, and season of the event.

Table 3.9-8 provides range to mortality and injury for all fishes. Only one table (Table 3.9-9) is provided for range to TTS for all fishes with a swim bladder. However, ranges to TTS for fishes with a swim bladder not involved in hearing would be shorter than those reported because this effect has not been observed in fishes without a swim bladder exposed to the described TTS threshold.

3.9.2.2.2.3 Impacts from Explosives Under Alternative 1

The following section provides estimated range to effects for fishes exposed to sound and energy produced by explosives. Ranges are calculated using criteria from Table 3.9-6 and Table 3.9-7 and the Navy Acoustic Effects Model. Most detonations conducted during Navy activities would occur at or near the surface. The Navy Acoustic Effects Model cannot account for the highly non-linear effects of cavitation and surface blow off; therefore, some estimated ranges may be overly conservative. Fishes within these ranges would be predicted to receive the associated effect. Ranges may vary greatly depending on factors such as the cluster size (the number of rounds fired [or buoys dropped] within a very short duration), location, depth, and season of the event.

Table 3.9-8: Range to Mortality and Injury for All Fishes from Explosives

Bin[1]	*Range to Effects (meters)*	
	Onset of Mortality	*Onset of Injury*
	SPL_{peak}	SPL_{peak}
E1	50 (45–50)	122 (120–130)
E2	63 (60–65)	156 (110–170)
E3	108 (100–110)	276 (260–280)
E4	141 (140–170)	381 (350–725)
E5	175 (170–250)	433 (410–775)
E6	218 (210–230)	526 (500–625)
E7	330 (330–330)	856 (825–875)
E8	375 (360–410)	920 (850–1,025)
E9	490 (480–500)	1,025 (1,025–1,025)
E10	617 (600–775)	1,388 (1,275–1,775)
E11	785 (700–1,525)	2,111 (1,525–4,775)
E12	770 (750–800)	1,781 (1,775–2,025)

[1]Bin (net explosive weight, lb.): E1 (0.1 – 0.25), E2 (> 0.25 – 0.5), E3 (> 0.5 – 2.5), E4 (> 2.5 – 5), E5 (> 5 – 10), E7 (> 20 – 60), E8 (> 60 – 100), E10 (> 250 – 500), E11 (> 500 – 650)

Notes: SPLpeak = Peak sound pressure level, NEW = net explosive weight, lb. = pound(s). Range to effects represent modeled predictions in different areas and seasons within the Study Area. Each cell contains the estimated average, minimum and maximum range to the specified effect.

Table 3.9-9: Range to TTS for Fishes with a Swim Bladder from Explosives

Bin[1]	*Cluster Size*	*Range to Effects (meters)*
		TTS
		SEL_{cum}
E1	1	< 50 (45–55)
	18	< 196 (160–230)
E2	1	< 58 (55–60)
E3	1	< 127 (95–160)
	19	< 474 (340–600)
E4	1	< 204 (190–300)
E5	1	< 172 (150–450)
	20	< 674 (525–2,775)
E6	1	< 210 (190–390)
E7	1	< 634 (600–725)
E8	1	< 527 (310–775)
E9	1	< 513 (420–1,025)
E10	1	< 685 (525–1,775)
E11	1	< 1,679 (1,525–2,775)
E12	1	< 815 (675–2,025)

[1]Bin (net explosive weight, lb.): E0 (< 0.1), E1 (0.1 – 0.25), E2 (> 0.25 – 0.5), E3 (> 0.5 – 2.5), E4 (> 2.5 – 5), E5 (> 5 – 10), E7 (> 20 – 60), E8 (> 60 – 100), E10 (> 250 – 500), E11 (> 500 – 650)
Notes: SELcum = Cumulative sound exposure level, TTS = Temporary Threshold Shift, NEW = net explosive weight, lb. = pound(s), "<" indicates that the given effect would occur at distances less than the reported range(s). Range to effects represent modeled predictions in different areas and seasons within the Study Area. Each cell contains the estimated average, minimum and maximum range to the specified effect.

Under Alternative 1, there could be fluctuation in the amount of explosions that could occur annually, although potential impacts would be similar from year to year. The number of impulsive sources in this SEIS/OEIS compared with the totals analyzed in the 2015 MITT Final EIS/OEIS are described in Table 2.5-1 and Table 2.5-2. The number of torpedo testing activities (both explosive and non-explosive) planned under Alternative 1 testing can vary from year to year; however, all other training and testing activities would remain consistent from year to year.

With the exception of mine warfare events which occur at the three established Underwater Detonation ranges, most scheduled training and testing activities involving explosions would occur well offshore (greater than 12 NM), primarily within special use airspace (e.g., W-517). Activities that involve underwater detonations and explosive munitions typically occur more than 3 NM from shore and in the range complexes, rather than in the transit corridor. The Navy will implement mitigation to avoid potential impacts on hammerhead sharks and giant manta rays in the Mariana Islands Range Complex during explosive mine neutralization activities involving Navy divers, as discussed in Section 5.3.3 (Explosive Stressors). In addition to procedural mitigation, the Navy will implement mitigation to avoid impacts from explosives on seafloor resources in mitigation areas throughout the Study Area (see Section 5.4.1, Mitigation Areas for Seafloor Resources), which will consequently also help avoid potential impacts on fishes that shelter and feed on shallow-water coral reefs, live hard bottom, artificial reefs, and shipwrecks.

Sound and energy from explosions could result in mortality and injury, on average, for hundreds to even thousands of meters from some of the largest explosions. Exposure to explosions could also result in temporary hearing loss in nearby fishes. The estimated range to each of these effects based on explosive bin size is provided in Table 3.9-8 and Table 3.9-9. Generally, explosives that belong to larger bins (with large net explosive weights) produce longer ranges within each effect category. However, some ranges vary depending upon a number of other factors (e.g., number of explosions in a single event, depth of the charge, etc.). Fishes without a swim bladder, adult fishes, and larger species would generally be less susceptible to injury and mortality from sound and energy associated with explosive activities than small, juvenile or larval fishes. Fishes that experience hearing loss could miss opportunities to detect predators or prey, or show a reduction in interspecific communication.

If an individual fish were repeatedly exposed to sound and energy from in-water explosions that caused alterations in natural behavioral patterns or physiological stress, these impacts could lead to long-term consequences for the individual such as reduced survival, growth, or reproductive capacity. If detonations occurred close together (within a few seconds), there could be the potential for masking to occur but this would likely happen at farther distances from the source where individual detonations might sound more continuous. Training and testing activities involving explosions are generally dispersed in space and time. Consequently, repeated exposure of individual fishes to sound and energy from in-water explosions over the course of a day or multiple days is not likely and most behavioral effects are expected to be short-term (seconds or minutes) and localized. Exposure to multiple detonations over the course of a day would most likely lead to an alteration of natural behavior or the avoidance of that specific area.

As discussed previously in Section 3.9.1.1 (Hearing and Vocalization), all ESA-listed fish species that occur in the Study Area are capable of detecting sound produced by explosives. In addition, all ESA-listed species that occur in the Study Area may be exposed to explosives associated with training and testing activities. The Indo-West Pacific Distinct Population Segment of scalloped hammerhead could occur in nearshore waters, such as bays and estuaries, but is also known to occur in offshore portions of the

Study Area. The giant manta ray and oceanic whitetip shark would most likely be exposed to low-frequency sonar in offshore areas throughout the Study Area. Overall, impacts on ESA-listed species that encounter explosions would be similar to those discussed above for impacts on fishes in general.

Pursuant to the ESA, the use of explosives during training and testing activities, as described under Alternative 1, may affect ESA-listed Indo-West Pacific Distinct Population Segment scalloped hammerhead sharks, oceanic whitetip sharks and giant manta rays.

3.9.2.2.2.4 Impacts from Explosives Under Alternative 2 (Preferred Alternative)

As described in Chapter 2 (Description of Proposed Action and Alternatives), Section 3.0.4.2 (Explosive Stressors), and Appendix A (Training and Testing Activities Descriptions), the number of activities that use explosives under Alternative 2 are consistent from year-to-year and would increase slightly compared to activities planned under Alternative 1. The differences in the number of events within the range complex across a year is nominal with only minor changes annually; therefore, the locations, tempo, and general types of predicted impacts would not be discernible from those described above in Section 3.9.2.2.2.3 (Impacts from Explosives Under Alternative 1 – Training Activities).

Pursuant to the ESA, the use of explosives during training and testing activities, as described under Alternative 2, may affect ESA-listed Indo-West Pacific Distinct Population Segment scalloped hammerhead sharks, oceanic whitetip sharks and giant manta rays. The Navy is consulting with NMFS as required by Section 7(a)(2) of the ESA.

3.9.2.2.2.5 Impacts from Explosives Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Explosive stressors, as described above, would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer explosive stressors within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for explosive impacts on individual fishes, but would not measurably improve the status of fish populations or subpopulations, including those listed under ESA and those federally managed under the MSA.

3.9.2.3 Energy Stressors

Energy stressors are discussed in Section 3.0.4.3. Energy stressors that may impact fishes include in-water electromagnetic devices and high-energy lasers. While the number of training and testing events would change under this SEIS/OEIS, the analysis presented in the 2015 MITT Final EIS/OEIS, Section 3.9.3.2 (Energy Stressors) remains valid. The changes in training and testing activities are not substantial and would not result in an appreciable change to existing environmental conditions or an increase in the level or intensity of energy stressors within the Study Area. High-energy lasers were not covered in the 2015 MITT Final EIS/OEIS and represent a new stressor analyzed in this SEIS/OEIS.

As discussed in Section 3.0.4.3.2.2 (High-Energy Lasers), high-energy laser weapons are designed to disable surface targets, rendering them immobile. Fish could be exposed to a laser only if the beam missed the target. Should the laser strike the sea surface, individual fish at or near the surface could be exposed. The potential for exposure to a high-energy laser beam decreases as the water depth

increases. Most fish are unlikely to be exposed to laser activities because they primarily occur more than a few meters below the sea surface.

3.9.2.3.1 Impacts from In-Water Electromagnetic Devices Under Alternative 1

Under Alternative 1, the number of proposed training and testing events involving the use of in-water electromagnetic devices would decrease in comparison to the 2015 MITT Final EIS/OEIS (Table 3.0-9). The activities would occur in the same locations and in a similar manner as were analyzed previously.

As stated in the 2015 MITT Final EIS/OEIS, in-water electromagnetic devices would not cause any potential risk to fishes because (1) the range of impact (i.e., greater than earth's magnetic field) is small (i.e., 13 ft. from the source), (2) the electromagnetic components of these activities are limited to simulating the electromagnetic signature of a vessel as it passes through the water, and (3) the electromagnetic signal is temporally variable and would cover only a small spatial range during each activity in the Study Area.

ESA-listed scalloped hammerhead sharks, oceanic whitetip sharks, and giant manta rays are capable of detecting electromagnetic energy. Therefore, energy stressors such as in-water electromagnetic devices could affect these species by causing temporary disturbances in their normal sensory perception during migratory or foraging movements, or avoidance reactions (Kalmijn, 2000). However, electromagnetic signals are temporally variable and would cover only a small spatial range during each activity in the Study Area. Therefore, impacts on fishes under Alternative 1 from in-water electromagnetic devices would be negligible.

Pursuant to the ESA, the use of in-water electromagnetic devices associated with training and testing activities, as described under Alternative 1, may affect ESA-listed Indo-West Pacific Distinct Population Segment of scalloped hammerhead sharks, oceanic whitetip sharks, and giant manta rays.

3.9.2.3.2 Impacts from In-Water Electromagnetic Devices Under Alternative 2 (Preferred Alternative)

Under Alternative 2, the number of proposed training and testing events involving the use of in-water electromagnetic devices would decrease in comparison to the 2015 MITT Final EIS/OEIS (Table 3.0-9). The activities would occur in the same locations and in a similar manner as were analyzed previously and above for Alternative 1.

Under Alternative 2, impacts on fishes from in-water electromagnetic devices should not be expected to occur and would be negligible.

Pursuant to the ESA, the use of in-water electromagnetic devices associated with training and testing activities, as described under Alternative 2, may affect ESA-listed Indo-West Pacific Distinct Population Segment of scalloped hammerhead sharks, oceanic whitetip sharks, and giant manta rays. The Navy is consulting with NMFS as required by Section 7(a)(2) of the ESA.

3.9.2.3.3 Impacts from In-Water Electromagnetic Devices Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Energy stressors as listed above would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer energy stressors within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for energy impacts on individual fishes, but would not measurably improve the status of fish populations or subpopulations, including those listed under ESA and those federally managed under the MSA.

3.9.2.3.4 Impacts from High-Energy Lasers Under Alternative 1

Under Alternative 1, the number of proposed events involving the use of high-energy lasers would be 54 (Table 3.0-10); this is a new substressor that was not analyzed in the 2015 MITT Final EIS/OEIS. As discussed above, the potential for fishes to be exposed to high-energy lasers is extremely low, and impacts from high-energy laser activities proposed under Alternative 1 should not be expected to occur. Therefore, impacts on fishes under Alternative 1 from high-energy lasers, would be negligible.

Pursuant to the ESA, the use of high-energy lasers during training and testing activities, as described under Alternative 1, may affect ESA-listed Indo-West Pacific Distinct Population Segment of scalloped hammerhead sharks, oceanic whitetip sharks, and giant manta rays.

3.9.2.3.5 Impacts from High-Energy Lasers Under Alternative 2 (Preferred Alternative)

Under Alternative 2, the number of proposed events involving the use of high-energy lasers would increase from 54 to 60 compared to Alternative 1 (Table 3.0-10) and the 2015 MITT Final EIS/OEIS; however, as discussed above, impacts on fishes from high-energy lasers should not be expected to occur. Therefore, impacts on fishes under Alternative 2 from energy stressors, including high-energy lasers, would be negligible.

Pursuant to the ESA, the use of high-energy lasers during training and testing activities, as described under Alternative 2, may affect ESA-listed Indo-West Pacific Distinct Population Segment of scalloped hammerhead sharks, oceanic whitetip sharks, and giant manta rays. The Navy is consulting with NMFS as required by Section 7(a)(2) of the ESA.

3.9.2.3.6 Impacts from High-Energy Lasers Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Energy stressors, as listed above, would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer energy stressors within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for energy impacts on individual fishes, but would not measurably improve the status of fish populations or subpopulations, including those listed under ESA and those federally managed under the MSA.

3.9.2.4 Physical Disturbance and Strike Stressors

Physical disturbance and strike stressors are discussed in Section 3.0.4.4. Physical disturbance and strike stressors that may impact fishes include (1) vessels and in-water devices, (2) military expended materials, and (3) seafloor devices. While the number of training and testing events would change under this SEIS/OEIS, the analysis presented in the 2015 MITT Final EIS/OEIS, Section 3.9.3.3 (Physical Disturbance and Strike) remains valid. The changes in training and testing activities are not substantial

and would not result in an overall change to existing environmental conditions or an increase in the level or intensity of physical disturbance and strike stressors within the Study Area.

As stated in the 2015 MITT Final EIS/OEIS, with few exceptions, activities involving vessels and in-water devices are not intended to contact the seafloor. There is minimal potential strike impact other than bottom-crawling unmanned underwater vehicles. Physical disturbance and strike stressors from vessels and in-water devices, military expended materials, and seafloor devices have the potential to affect all marine fish groups found within the Study Area, although some fish groups may be more susceptible to strike potential than others. In addition, the potential responses to physical strikes are varied, but include behavioral changes such as avoidance, altered swimming speed and direction, physiological stress, and physical injury or mortality.

3.9.2.4.1 Impacts from Physical Disturbance and Strike Stressors Under Alternative 1

Under Alternative 1, the combined number of proposed training and testing events involving vessels and in-water devices would decrease slightly from those presented in the 2015 MITT Final EIS/OEIS (Table 3.0-12 and Table 3.0-13). Military expended materials (Table 3.0-14, Table 3.0-15, and Table 3.0-16) combined would generally increase, and seafloor devices (Table 3.0-19) would decrease slightly from the number in the 2015 MITT Final EIS/OEIS. Increases in physical disturbance and strike stressors, such as military expended materials, could increase the level of impact on some fishes. Analysis by individual category of expended items indicates that those items having the most potential to affect fishes have decreased. Overall, these changes do not appreciably change the analysis or impact conclusions presented in the 2015 MITT Final EIS/OEIS because the impact analysis was based on the probability of an impact on a resource.

The risk of a strike from vessels and in-water devices used in training and testing activities on an individual fish would be extremely low because (1) most fish can detect and avoid vessel and in-water device movements, and (2) the types of fish that are likely to be exposed to vessel and in-water device strike are limited and occur in low concentrations where vessels and in-water devices are used. Potential impacts of exposure to vessels and in-water devices are not expected to result in substantial changes to an individual's behavior, fitness, or species recruitment, and are not expected to result in population-level impacts. Therefore, impacts on fish or fish populations would be negligible.

Similar to most other fish species described above, ESA-listed scalloped hammerhead sharks, oceanic whitetip sharks, and giant manta rays, would be able to sense pressure changes in the water column and swim quickly, and are likely to escape collision with vessels and in-water devices.

Therefore, under Alternative 1, impacts on fishes from the use of vessels and in-water devices, military expended materials, and seafloor devices would be negligible.

Pursuant to the ESA, the use of vessels and in-water devices associated with training and testing activities, as described under Alternative 1, may affect ESA-listed Indo-West Pacific Distinct Population Segment of scalloped hammerhead sharks, oceanic whitetip sharks, and giant manta rays.

3.9.2.4.2 Impacts from Physical Disturbance and Strike Stressors Under Alternative 2 (Preferred Alternative)

Under Alternative 2, the combined number of proposed training and testing events involving vessels and in-water devices would decrease slightly from those presented in the 2015 MITT Final EIS/OEIS (Table 3.0-12 and Table 3.0-13). Military expended materials (Table 3.0-14, Table 3.0-15, and Table 3.0-16) combined would generally increase, and seafloor devices (Table 3.0-19) would decrease slightly from the number in the 2015 MITT Final EIS/OEIS. Increases in some physical disturbance and

strike stressors such as military expended materials could increase the impact risk on fishes but does not appreciably change the analysis or impact conclusions presented in the 2015 MITT Final EIS/OEIS. Impacts on fishes would be inconsequential for the same reasons detailed above and would have no appreciable change on the impact conclusions for physical disturbance and strike stressors, as presented in the 2015 MITT Final EIS/OEIS and summarized above under Alternative 1.

Therefore, under Alternative 2, impacts on fishes from physical disturbance and strike would be negligible.

Pursuant to the ESA, the use of vessels and in-water devices associated with training and testing activities, as described under Alternative 2, may affect ESA-listed Indo-West Pacific Distinct Population Segment of scalloped hammerhead sharks, oceanic whitetip sharks, and giant manta rays. The Navy is consulting with NMFS as required by Section 7(a)(2) of the ESA.

3.9.2.4.3 Impacts from Physical Disturbance and Strike Stressors Under the No Action Alternative

Under the No Action Alternative, proposed training and testing. Other military activities not associated with this Proposed Action would continue to occur. Physical disturbance and strike stressors as listed above would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer physical disturbance and strike stressors within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for physical disturbance and strike impacts on individual fishes, but would not measurably improve the status of fish populations or subpopulations, including those listed under ESA and those federally managed under the MSA.

3.9.2.5 Entanglement Stressors

Entanglement stressors are discussed in Section 3.0.4.5. Entanglement stressors considered for fishes include (1) fiber optic cable and guidance wires, and (2) decelerators/parachutes. The annual number of wires and cables and decelerators/parachutes proposed under the alternatives and in comparison to current ongoing activities are presented in Tables 3.0-20, 3.0-21, and 3.0-22. There have been no known instances of any fish being entangled in wires and cables, or decelerators/parachutes associated with Navy training and testing activities prior to or since the 2015 MITT Final EIS/OEIS.

3.9.2.5.1 Impacts from Entanglement Stressors Under Alternative 1

Under Alternative 1, the combined number of fiber optic cables (Table 3.0-22) decrease, guidance wires (Table 3.0-22) increase, and decelerators/parachutes (Table 3.0-24) decrease compared to the number of events proposed in the 2015 MITT Final EIS/OEIS. Decreases in the number of training and testing events would potentially decrease the level of entanglement stressors on fishes in the Study Area.

As stated in the 2015 MITT Final EIS/OEIS, while individual fish susceptible to entanglement would encounter wires and cables, including guidance wires, fiber optic cables, and sonobuoy wires during training and testing activities, the long-term consequences of entanglement are unlikely for either individuals or populations because (1) the encounter rate for wires and cables is low, (2) the types of fishes that are susceptible to these items is limited, (3) there is restricted overlap with susceptible fishes, and (4) the physical characteristics of the wires and cables reduce entanglement risk to fishes compared

to monofilament used for fishing gear. Potential impacts from exposure to fiber optic cables and guidance wires are not expected to result in substantial changes to an individual's behavior, fitness, or species recruitment, and are not expected to result in population-level impacts.

As described in the 2015 MITT Final EIS/OEIS, it would be very unlikely that fishes would encounter and become entangled in any decelerators/parachutes or sonobuoy accessories. This is mainly due to the size of the range complexes and the resulting widely scattered decelerators/parachutes. If a few individual fish were to encounter and become entangled in a decelerator/parachute, the growth, survival, annual reproductive success, or lifetime reproductive success of the population as a whole would not be impacted directly or indirectly.

Therefore, impacts on fishes under Alternative 1 from the use of fiber optic cables and guidance wires and decelerators/parachutes would be negligible.

Pursuant to the ESA, the use of fiber optic cables and guidance wires and decelerators/parachutes associated with training and testing activities, as described under Alternative 1, may affect ESA-listed Indo-West Pacific Distinct Population Segment of scalloped hammerhead sharks, oceanic whitetip sharks, and giant manta rays.

3.9.2.5.2 Impacts from Entanglement Stressors Under Alternative 2 (Preferred Alternative)

Under Alternative 2, the combined number of entanglement stressors decrease (Table 3.0-22 through Table 3.0-24) compared to the number of events proposed in the 2015 MITT Final EIS/OEIS and would increase or stay the same compared to Alternative 1. However, as stated above for Alternative 1, training and testing activities involving fiber optic cables, guidance wires, and decelerators/parachutes are not expected to impact an individual's behavior, fitness, or species recruitment, and are not expected to result in population-level impacts.

Therefore, impacts on fishes from entanglement stressors such as wires and cables and decelerators/parachutes under Alternative 2 would be negligible.

Pursuant to the ESA, the use of fiber optic cables and guidance wires and decelerators/parachutes associated with training and testing activities, as described under Alternative 2, may affect ESA-listed Indo-West Pacific Distinct Population Segment of scalloped hammerhead sharks, oceanic whitetip sharks, and giant manta rays. The Navy is consulting with NMFS as required by Section 7(a)(2) of the ESA.

3.9.2.5.3 Impacts from Entanglement Stressors Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Entanglement stressors as listed above would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer physical disturbance and strike stressors within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for entanglement impacts on the fishes from entanglement, but would not measurably improve the status of fish populations or subpopulations, including those listed under ESA and those federally managed under the MSA.

3.9.2.6 Ingestion Stressors

Ingestion stressors (military expended materials – munition and military expended materials – other than munition) are discussed in Section 3.0.4.6. Ingestion stressors that may impact fishes include various types of military expended materials such as munitions and expended materials other than munitions used by the Navy during training and testing activities within the Study Area. While the number of training and testing events would change under this SEIS/OEIS, the analysis presented in the 2015 MITT Final EIS/OEIS, Section 3.9.3.2 (Ingestion Stressors) remains valid. The changes in training and testing activities are not substantial and would not result in an appreciable change to existing environmental conditions or an increase in the amount of ingestion stressors within the Study Area.

3.9.2.6.1 Impacts from Ingestion Stressors Under Alternative 1

Under Alternative 1, the combined number of ingestion stressors would increase compared to the number in the 2015 MITT Final EIS/OEIS (see Table 3.0-14, Table 3.0-15, Table 3.0-16, Table 3.0-25, and Table 3.0-26). However, increases in the number of ingestion stressors do not appreciably change the impact analysis or conclusions presented in the 2015 MITT Final EIS/OEIS.

As presented in the 2015 MITT Final EIS/OEIS, open-ocean predators and open-ocean planktivores are most likely to ingest materials in the water column, while coastal bottom-dwelling predators and estuarine bottom-dwelling predators could ingest materials from the seafloor. Open-ocean predators such as tunas and sharks may eat floating or sinking expended materials, while open-ocean planktivores, such as sardines and filter-feeding species such as whale sharks, may ingest floating expended materials incidentally as they feed in the water column. Other fish species such as skates and rays forage on the seafloor and may ingest expended materials on the seafloor. Encounter rates for all of these feeding guilds would be extremely low, but may result in injury or death to individuals; however, population-level effects are not anticipated.

Potential impacts of ingestion on some adult fishes are different than for other life stages (eggs, larvae, and juveniles) because early life stages for some species are too small to ingest any military expended materials except for chaff, which has been shown to have limited effects on fishes in the concentration levels that it is released at (Arfsten et al., 2002; U.S. Department of the Air Force, 1997; U.S. Department of the Navy, 1999). Therefore, with the exception of later stage larvae and juveniles that could ingest microplastics, no ingestion potential impacts on early life stages are expected.

Overall, the potential impacts of ingesting expended military materials such as munitions or other expended materials, such as chaff and flare end caps and pistons, would be limited to individual fish that might suffer a negative response from a given ingestion event. While ingestion of military expended materials could result in sublethal or lethal effects to a small number of individuals, the likelihood of a fish encountering an expended item is dependent on where that species feeds and the amount of material expended. Furthermore, an encounter may not lead to ingestion, as a fish might “taste” an item, then expel it (Felix et al., 1995), in the same manner that a fish would take a lure into its mouth then spit it out.

Therefore, the number of fishes potentially impacted by ingestion of military expended materials such as munitions and other expended materials would be negligible.

Pursuant to the ESA, the use of military expended materials associated with training and testing activities, as described under Alternative 1, may affect ESA-listed Indo-West Pacific Distinct Population Segment of scalloped hammerhead sharks, oceanic whitetip sharks, and giant manta rays.

3.9.2.6.2 Impacts from Ingestion Stressors Under Alternative 2 (Preferred Alternative)

Under Alternative 2, the combined number of ingestion stressors would increase compared to the number proposed for use in the 2015 MITT Final EIS/OEIS and above for Alternative 1 (see Table 3.0-14, Table 3.0-15, Table 3.0-16, Table 3.0-25, and Table 3.0-26). However, these increases do not appreciably change the impact analysis or conclusions presented in the 2015 MITT Final EIS/OEIS and presented above under Alternative 1.

Therefore, impacts on fishes from ingestion of military expended materials under Alternative 2 would be negligible.

Pursuant to the ESA, the use of military expended materials associated with training and testing activities, as described under Alternative 2, may affect ESA-listed Indo-West Pacific Distinct Population Segment of scalloped hammerhead sharks, oceanic whitetip sharks, and giant manta rays. The Navy is consulting with NMFS as required by Section 7(a)(2) of the ESA.

3.9.2.6.3 Impacts from Ingestion Stressors Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Ingestion stressors as listed above would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer ingestion stressors within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for ingestion impacts on the fishes from ingestion of military expended material, but would not measurably improve the status of fish populations or subpopulations, including those listed under ESA and those federally-managed under the MSA.

3.9.2.7 Secondary Stressors

Secondary stressors from training and testing activities that could pose secondary or indirect impacts on fishes via habitat, prey, sediment, and water quality include (1) explosives and byproducts; (2) metals; (3) chemicals; (4) other materials such as targets, chaff, and plastics; and (5) impacts on fish habitat. While the number of training and testing events would change under this SEIS/OEIS, the analysis presented in the 2015 MITT Final EIS/OEIS, Section 3.9.3.6 (Secondary Stressors) remains valid. The changes in training and testing activities are not substantial and would not result in an appreciable change to existing environmental conditions or an increase in the level or intensity of energy stressors within the Study Area.

As stated in the 2015 MITT Final EIS/OEIS, indirect impacts of explosives and unexploded ordnance on fishes via water could not only cause physical impacts, but prey might also have behavioral reactions to underwater sound. For example, the sound from underwater explosions might induce startle reactions and temporary dispersal of schooling fishes if they are within close proximity. The abundances of fish and invertebrate prey species near the detonation point could be diminished for a short period of time before being repopulated by animals from adjacent waters. Secondary impacts from underwater explosions would be temporary, and no lasting impact on prey availability or the pelagic food web would be expected. Indirect impacts of underwater detonations and explosive ordnance use under the

Proposed Action would not result in a decrease in the quantity or quality of fish populations or fish habitats in the Study Area.

Indirect impacts of explosives and unexploded ordnance to fishes via sediment is possible in the immediate vicinity of the ordnance. Degradation of explosives proceeds via several pathways discussed in Section 3.1 (Sediments and Water Quality). Degradation products of Royal Demolition Explosive are not toxic to marine organisms at realistic exposure levels (Rosen & Lotufo, 2010). TNT and its degradation products impact developmental processes in fishes and are acutely toxic to adults at concentrations similar to real-world exposures (Halpern et al., 2008; Rosen & Lotufo, 2010). It is likely that various lifestages of fishes could be impacted by the indirect impacts of degrading explosives within a very small radius of the explosive (1–6 ft.), but these impacts are expected to be short term and localized.

Certain metals are harmful to fishes at concentrations above background levels (e.g., cadmium, chromium, lead, mercury, zinc, copper, manganese, and many others) (Wang & Rainbow, 2008). Metals are introduced into seawater and sediments as a result of Navy training and testing activities involving vessel hulks, targets, ordnance, munitions, and other military expended materials. Indirect impacts of metals to fishes via sediment and water involve concentrations that are several orders of magnitude lower than concentrations achieved via bioaccumulation. Fishes may be exposed by contact with the metal, contact with contaminants in the sediment or water, and ingestion of contaminated sediments. Concentrations of metals in sea water are orders of magnitude lower than concentrations in marine sediments. It is extremely unlikely that fishes would be indirectly impacted by toxic metals via the water.

Several training and testing activities introduce potentially harmful chemicals into the marine environment; principally, flares and propellants for rockets, missiles, and torpedoes. The greatest risk to fishes from flares, missile, and rocket propellants is perchlorate, which is highly soluble in water, persistent, and impacts metabolic processes in many plants and animals. Fishes may be exposed by contact with contaminated water or ingestion of contaminated sediments. Since perchlorate is highly soluble, it does not readily absorb to sediments. Therefore, missile and rocket fuel pose no risk of indirect impact on fishes via sediment. In contrast, the principal toxic components of torpedo fuel, propylene glycol dinitrate and nitrodiphenylamine, adsorbs to sediments, has relatively low toxicity, and is readily degraded by biological processes. It is conceivable that various lifestages of fishes could be indirectly impacted by propellants via sediment in the immediate vicinity of the object (e.g., within a few inches), but these potential impacts would diminish rapidly as the propellant degrades.

As described in the 2015 MITT Final EIS/OEIS, some military expended materials (e.g., decelerators/parachutes) could become remobilized after their initial contact with the sea floor (e.g., by waves or currents) and could be reintroduced as an entanglement or ingestion hazard for fishes. In some bottom types (without strong currents, hard-packed sediments, and low biological productivity), items such as projectiles might remain intact for some time before becoming degraded or broken down by natural processes. While these items remain intact sitting on the bottom, they could potentially remain ingestion hazards. These potential impacts may cease only (1) when the military expended materials is too massive to be mobilized by typical oceanographic processes, (2) if the military expended materials become encrusted by natural processes and incorporated into the seafloor, or (3) when the military expended materials become permanently buried. In this scenario, a parachute could initially sink to the seafloor, but then be transported laterally through the water column or along the seafloor, increasing the opportunity for entanglement. In the unlikely event that a fish would

become entangled, injury or mortality could result. The entanglement stressor would eventually cease to pose an entanglement risk as it becomes encrusted or buried, or degrades.

Secondary stressors can also involve impacts on habitat (sediment or water quality) or prey (i.e., impacting the availability or quality of prey) that have the potential to affect fish species, including ESA-listed scalloped hammerhead sharks, oceanic whitetip sharks, and manta rays. Secondary stressors that may affect ESA-listed species only include those related to the use of explosives. Secondary effects on prey and habitat from the release of metals, chemicals, and other materials into the marine environment during training and testing activities are not anticipated. In addition to directly impacting ESA-listed species, underwater explosives could impact other species in the food web, including those that these species prey upon. The impacts of explosions would differ depending upon the type of prey species in the area of the blast. In addition to physical effects of an underwater blast, prey might have behavioral reactions to underwater sound. For instance, prey species might exhibit a strong startle reaction to explosions that might include swimming to the surface or scattering away from the source. This startle and flight response is the most common secondary defense among animals. The abundances of prey species near the detonation point could be diminished for a short period of time, affecting prey availability for ESA-listed species feeding in the vicinity. Any effects to prey, other than prey located within the impact zone when the explosive detonates, would be temporary. The likelihood of direct impacts on fishes and mobile invertebrates is low, as described in this section. No lasting effects on prey availability or the pelagic food web would be expected.

3.9.3 Public Comments

The public raised a number of issues during the scoping period in regards to fishes. The issues are summarized in the list below. Comments received from the public during the Draft SEIS/OEIS commenting period related to fishes are addressed in Appendix K (Public Comment Responses).

- **Acoustic and explosive disturbance to fish and EFH –** As described in the 2015 MITT Final EIS/OEIS, and documented in Section 3.9.2.1 (Acoustic Stressors), Navy training and testing activities may affect individual fish by causing some minor behavioral reactions. However, these activities would not cause a population-level impact. For federally managed fish species and habitats under the MSA, those impacts are detailed in Chapter 6. The Navy would also use mitigation measures detailed in Chapter 5 (Mitigation) to reduce potential impacts on less than significant levels. For example, during Explosive Mine Neutralization Activities involving Navy divers, divers will notify their supporting small boat or Range Safety Officer of hammerhead shark sightings (of any hammerhead species, due to the difficulty of differentiating species) at the detonation location. The Navy will delay fuse initiations or detonations until the shark is observed exiting the detonation location.
- **Direct and cumulative impacts from military-expended material and debris on marine biology –** As described in the 2015 MITT Final EIS/OEIS and above, military expended material may affect marine biological resources such as fishes through physical disturbance and strike, entanglement, ingestion, and have a cumulative effect on these resources. However, due to the low potential for interaction between biological resources and entanglement, ingestion, and strike stressors for reasons discussed above and in the 2015 MITT Final EIS/OEIS, military expended materials are not expected to pose a significant risk to the marine resources, including fishes.

- **Direct and cumulative impacts on fish populations –** As described in the 2015 MITT Final EIS/OEIS and in most sections above, impacts on fish from acoustic and explosive stressors (Section 3.9.2.1, Acoustic Stressors, and Section 3.9.2.2, Explosive Stressors) may injure or kill a few individuals but are unlikely to have measurable impacts on overall stocks or populations, including ESA-listed scalloped hammerhead sharks, oceanic whitetip sharks, and giant manta rays. As stated in the 2015 MITT Final EIS/OEIS, if an underwater explosion occurred in an area of high fish density, then more fish would be impacted; however, the probability of this occurring is low based on the patchy distribution of dense schooling fish. In addition, near shore areas used for underwater seafloor detonations are areas that have been previously disturbed and unlikely to support large schools or groups of fish. Cumulative impacts may affect individual fish, but would not have population-level impacts.
- **Impacts on marine species from the metals in the water (copper and lead) (see Section 3.9.2.7, Secondary Stressors) –** As described in the 2015 MITT Final EIS/OEIS and above, metals would be introduced into seawater and sediments as a result of Navy training and testing activities involving vessel hulks, targets, ordnance, munitions, and other military expended materials. Fishes may be exposed by contact with the metal, contact with contaminants in the sediment or water, and ingestion of contaminated sediments. Concentrations of metals in sea water are orders of magnitude lower than concentrations in marine sediments. It is extremely unlikely that fishes would be indirectly impacted by toxic metals via the water.

3.10 Terrestrial Species and Habitats

3.10.1 Affected Environment

The purpose of this section is to supplement the analysis of impacts on terrestrial species and habitats presented in the 2015 *Mariana Islands Training and Testing (MITT) Final Environmental Impact Statement/Overseas Environmental Impact Statement* (EIS/OEIS) with new information relevant to proposed changes in training activities conducted at Farallon de Medinilla (FDM). Information presented in the 2015 MITT Final EIS/OEIS that remains valid is noted as such and referenced in the appropriate sections. Any new or updated information describing the affected environment and analysis of impacts on terrestrial species and habitats associated with the Proposed Action is provided in this section. Comments received from the public during scoping related to terrestrial species and habitats are addressed in Section 3.10.3 (Public Comments). Comments received from the public during the Draft Supplemental EIS (SEIS)/OEIS commenting period related to terrestrial species and habitats are addressed in Appendix K (Public Comment Responses).

Section 3.10 in the 2015 MITT Final EIS/OEIS analyzed the potential impacts of training activities on three Endangered Species Act (ESA)-listed plant species (*Serianthes nelsonii*, *Osmoxylon mariannense,* and *Nesogenes rotensis*), eight bird species typically found in terrestrial habitats[1] (Mariana swiftlet [*Aerodramus bartschi*], Mariana crow [*Corvus kubaryi*], Mariana common moorhen, [*Gallinula chloropus guami*], Guam Micronesian kingfisher [*Todiramphus cinnamomina*], Micronesian megapode [*Megapodius laperouse*], Guam rail [*Rallus owstoni*], Nightingale reed-warbler [*Acrocephalus luscinia*], and Rota bridled white-eye [*Zosterops rotensis*]), and one mammal species (Mariana fruit bat [*Pteropus mariannus*]). Of these species, only the Micronesian megapode and Mariana fruit bat are found on FDM; therefore, only these ESA-listed species are included in the Navy's SEIS/OEIS (Table 3.10-1). FDM has no critical habitat designations on the island; therefore, critical habitat is not addressed in this SEIS/OEIS.

In addition to the analysis completed for ESA-listed species, the Navy's 2015 MITT Final EIS/OEIS also considered species that at the time were candidates for ESA listing status. Since the publication of the 2015 MITT Final EIS/OEIS, the United States Fish and Wildlife Service (USFWS) has published its Final Rule determining ESA listing status for 23 additional species in the Mariana Islands (80 Federal Register 59423). Because some of these newly listed species were known to occur within the land training areas analyzed in the 2015 MITT Final EIS/OEIS, the Navy and the USFWS reinitiated consultation to include 14 plant species (*Bulbophyllum guamense, Cycas micronesica, Dendrobium guamense, Eugenia bryanii, Heritiera longipetiolata, Maesa walker, Nervilia jacksoniae, Psychotria malaspinae, Solanum guamense, Tabernaemontana rotensis, Tinospora homosepala, Tuberolabium guamense, Hedyotis megalantha*, *Phyllanthus saffordii*) and four terrestrial invertebrates (Mariana eight-spot butterfly [*Hypolimnas octocula marianensis*], Guam tree snail [*Partula radiolata*], fragile tree snail [*Samoana fragilis*], and humped tree snail [*Partula gibba*]). The USFWS concurred with the Navy's determination that the activities originally proposed in the Navy's 2015 MITT Final EIS/OEIS would not adversely affect these

[1] The 2015 MITT Final EIS/OEIS analyzed bird species in two different sections. In the 2015 MITT Final EIS/OEIS, birds that typically depend on non-marine habitats were analyzed together with other terrestrial plant and animal species (see Section 3.10 of the 2015 MITT Final EIS/OEIS). Marine birds were analyzed separately in Section 3.6 (Marine Birds) of the 2015 MITT Final EIS/OEIS. These species include birds that occur only in pelagic habitats within the Study Area, as well as marine birds that nest within the Study Area. This SEIS/OEIS follows this organization.

newly listed species and that species and habitat protections described in the 2015 MITT Final EIS/OEIS would also protect newly listed species (U.S. Fish and Wildlife Service, 2016). FDM is not included in the range for any of these species (80 Federal Register 59423) and, based on the structure and composition of the remnant forest on the island, it is extremely unlikely that there is habitat for any of these species on FDM. Therefore, none of these species are included in this SEIS/OEIS. Review of the 2015 MITT Final EIS/OEIS confirms the analysis for these species in that document is accurate and represents the best available science.

Table 3.10-1: Endangered Species Act Listed Species on Farallon de Medinilla

Species Name and Regulatory Status			Presence in Study Area[1]	
Common Name	**Scientific Name**	**Endangered Species Act Status**	**Open Ocean**	**Visitor/Breeding on FDM**
Micronesian megapode (Sasangat)	*Megapodius laperouse*	Endangered	Yes	Yes
Mariana fruit bat (Fanihi)	*Pteropus mariannus*	Threatened	Yes	Yes, possible breeding

[1]Study Area = Mariana Islands Training and Testing Study Area
Note: FDM = Farallon de Medinilla

3.10.1.1 Vegetation Communities on Farallon de Medinilla

The United States (U.S.) military has used the island of FDM as a bombing range since 1971 (U.S. Department of the Navy, 1975), and the agreement between the U.S. Government and the Commonwealth of the Northern Mariana Islands was formalized in a 50-year lease agreement (United States of America and Commonwealth of the Northern Mariana Islands, 1983). FDM's vegetation appears to have undergone significant changes since the island was leased by the Department of Defense and the subsequent bombardment for military training. The most intensive bombardment to date of FDM occurred during the Vietnam era, when as much as 22 tons of ordnance per month were dropped on the island (Lusk et al., 2000). Based on early 20th century descriptions of FDM vegetation and aerial photographs of the island prior to military bombardment activities, island tree height and canopy cover have been greatly reduced (Lusk et al., 2000; Mueller-Dombois & Fosberg, 1998; Mueller-Dombois & Fosberg, 2013).

The island's vegetation may be grouped into the following vegetation communities: coastal vegetation, cliff-line vegetation, upland shrubland and herbaceous vegetation, and bare ground exposed within impact zones. A brief botanical survey of the northern portion of the island carried out in 1996 identified 43 plant species, 32 of which were native (Mueller-Dombois & Fosberg, 1998; Mueller-Dombois & Fosberg, 2013). Periodic helicopter-based surveys have occurred since 1998 (monthly up to 2009, and quarterly thereafter through September 2016) for marine birds on the island. Although the primary goal of these surveys is to count three species of boobies (stationary on the island and not on the wing), observations of other species observed and general observations of vegetation condition are made during the surveys. Because of continued access constraints associated with the unexploded ordnance risk, no formal plant surveys have been completed on FDM since the publication of the 2015 MITT Final EIS/OEIS. Because of a lack of commercial helicopter transit services, surveys have not been conducted since 2016. The most recent surveys have not provided any indications that the vegetation communities have changed since the 2015 MITT Final EIS/OEIS.

3.10.1.2 Wildlife Communities on Farallon de Medinilla

3.10.1.2.1 Birds

FDM is recognized by regional ornithologists as an important bird area for many species of marine birds and migrant shorebirds, and supports a limited number of terrestrial bird species (Lusk et al., 2000; U.S. Department of the Navy, 2019; U.S. Fish and Wildlife Service, 1998). Seabird and shorebird species are discussed in Section 3.6 (Marine Birds) of this SEIS/OEIS. No new information is available since the publication of the 2015 MITT Final EIS/OEIS regarding FDM's terrestrial avifauna; therefore, the description of the avian portion of FDM's wildlife community in the 2015 MITT Final EIS/OEIS remains valid. (Lusk et al., 2000; U.S. Department of the Navy, 2013, 2019).

3.10.1.2.2 Mammals

Incidental observations of fruit bats during bird surveys described in the 2015 MITT Final EIS/OEIS, along with fishermen reports from the early 1970s, suggest a small number of fruit bats use FDM, possibly as a stopover location while transiting between islands. Fruit bats are discussed in more detail below. The only other mammalian species known to occur on the island are introduced small-sized rats, believed to be *Rattus exulans*. Commonly observed during past natural resource surveys (U.S. Department of the Navy, 2008a, 2013), it is believed that rats negatively impact breeding activities for seabirds, and upland terrestrial birds on the island. There is no new information available that would inform the impact analysis on FDM's mammals since the publication of the 2015 MITT Final EIS/OEIS; therefore, the description of the mammalian portion of FDM's wildlife community in the 2015 MITT Final EIS/OEIS remains valid.

3.10.1.2.3 Reptiles and Amphibians

Only two species of reptiles are reported on FDM—the Pacific blue-tailed skink (*Emoia caeruleocauda*) and the oceanic snake-eyed skink (*Cryptoblepharus poecilopleurus*) (U.S. Department of the Navy 2008a). No observations of brown treesnakes have been reported on the island. No new information has become available since the publication of the 2015 MITT Final EIS/OEIS that expands upon the known list of reptiles on FDM; therefore, the description of FDM's reptiles and amphibians in the 2015 MITT Final EIS/OEIS remains valid.

3.10.1.2.4 Invertebrates

Since the publication of the 2015 MITT Final EIS/OEIS, no new inventories for invertebrate species have been conducted on FDM. Prior to the 2015 MITT Final EIS/OEIS, no formal surveys for invertebrates were conducted; accounts of invertebrates have been provided as incidental observations during other natural resource survey efforts. For instance, coconut crabs, including one female with eggs, were observed on FDM in August 2008 (U.S. Department of the Navy, 2013).

3.10.1.3 Endangered Species Act Listed Species

3.10.1.3.1 Micronesian Megapode/Sasangat (*Megapodius laperouse laperouse*)

The Micronesian megapode was first listed as endangered in 1970 (under the Endangered Species Conservation Act, 35 Federal Register 8491–8498). No critical habitat is designated for this species. Threats to this species include habitat loss from typhoons and volcanic activity, damage by feral herbivores, hunting and illegal egg collection, increased tourism, and predation by introduced predators (U.S. Fish and Wildlife Service, 1998). Small remnant populations are known to exist on the southern Mariana Islands of Aguiguan, Saipan, and FDM; larger populations are reported on uninhabited northern islands of Anatahan, Guguan, Sarigan, Alamagan, Pagan, Asuncion, Maug, and possibly Agrihan (Amidon

et al., 2011; U.S. Department of the Navy, 2019). Recent surveys and modeling suggests that islands with low human presence and without ungulates have the highest densities of megapodes (i.e., Maug, Asuncion, Guguan, and Sarigan) (Amidon et al., 2011).

Surveys on FDM in 1996 documented the presence of the Micronesian megapode (Lusk et al., 2000; U.S. Fish and Wildlife Service, 1998). From this survey, a population of 10 Micronesian megapodes was estimated on FDM (Kessler & Amidon, 2009; Lusk et al., 2000; U.S. Fish and Wildlife Service, 1998). However, due to an approaching typhoon, biologists were only on the island for about 5.5 hours, so this estimate was based on limited data. FDM was surveyed more thoroughly in December 2007 by Navy biologists, who estimated 21 adult pairs (U.S. Department of the Navy, 2008b, 2008c). The most recent survey for megapodes on FDM was completed in 2013, when Navy biologists detected 11 megapodes while surveying a limited transect in the north part of the island (Impact Areas 1 and 2) (U.S. Department of the Navy, 2013).

Poaching has been identified as a potential threat to megapodes in the northern Mariana Islands (Reichel, 1991; U.S. Fish and Wildlife Service, 1998). Mitigation measures specified in previous consultations coupled with the restricted access preventing poaching activities may have benefited megapodes on FDM. The mitigation measures included maintaining a no-fire zone on the northern portion of the island and the use of inert ordnance in an area south of the no-fire zone (explosive ordnance is deployed south of this area). These measures were included as non-discretionary terms and conditions in the USFWS's biological opinion for activities consulted on in 2015.

Since the publication of the 2015 MITT Final EIS/OEIS, there is no new information available to further expand the life history and status of the Micronesian megapodes on FDM. Therefore, the information in the 2015 MITT Final EIS/OEIS is valid for analyzing potential impacts on the Micronesian megapode.

3.10.1.3.2 Mariana Fruit Bat/Fanihi (*Pteropus mariannus mariannus*)

The Guam population of the Mariana fruit bat (Mariana flying fox) was federally listed as endangered in 1984 (U.S. Fish and Wildlife Service, 2009). However, in 2005, the Mariana fruit bat was listed as threatened throughout the Mariana archipelago and downlisted to threatened on Guam. The recovery plan for the Mariana fruit bat was first finalized in 1990; however, a draft revised recovery plan for the Mariana fruit bat was released in March 2010. Critical habitat is designated on Guam and Rota, but there is no critical habitat designated on FDM.

Since the publication of the 2015 MITT Final EIS/OEIS, no new information on the Mariana fruit bat life history or status on FDM is available. Therefore, the information in the 2015 MITT Final EIS/OEIS is valid for analyzing potential impacts on the Mariana fruit bat.

3.10.1.4 Major Terrestrial Species Taxonomic Group Descriptions

There have been no updates to the status and life history descriptions for the major taxonomic groups that occur within Mariana Island terrestrial environments since the publication of the 2015 MITT Final EIS/OEIS.

3.10.2 Environmental Consequences

The 2015 MITT Final EIS/OEIS analyzed training and testing activities currently occurring in the MITT Study Area and considered all potential stressors related to terrestrial biological resources. Stressors applicable to terrestrial biological resources on FDM are the same stressors analyzed in the 2015 MITT Final EIS/OEIS. For this supplemental analysis, explosives, which were analyzed under acoustic stressors in 2015, are now analyzed as a separate stressor.

In addition, the 2015 MITT Final EIS/OEIS assessed potential impacts on training locations on Guam, Rota, Tinian, Saipan, and FDM, whereas this SEIS/OEIS only updates the analysis on FDM.

The following stressors are analyzed for terrestrial biological resources; the analyses include stressor description updates from the 2015 MITT Final EIS/OEIS:

- Acoustic (weapons noise)
- Explosives (explosions on land at FDM)
- Physical Disturbance and Strike (aircraft and aerial targets, military expended materials, ground disturbance, and wildfires)
- Secondary stressors (impacts on habitat, impacts on prey availability, introduction of potential invasive species)

This section evaluates how and to what degree potential impacts on terrestrial biological resources from stressors described in Section 3.0 (Introduction) may have changed since the analysis presented in the 2015 MITT Final EIS/OEIS was published. Table 2.5-1 in Chapter 2 (Description of Proposed Action and Alternatives) lists the proposed training activities that would occur on FDM and includes the number of times each activity would be conducted annually under each alternative. The tables also present the same information for activities described in the 2015 MITT Final EIS/OEIS so that the proposed levels of training and testing under this SEIS/OEIS can be easily compared.

The analysis presented in this section also considers measures that the Navy would implement to avoid or reduce potential impacts on terrestrial biological resources on FDM from stressors associated with the proposed training activities. As with the 2015 MITT Final EIS/OEIS, no testing activities would occur on FDM.

3.10.2.1 Acoustic Stressors

The potential impacts of explosives noise and weapons firing noise on FDM's wildlife are discussed in Section 3.10.3.1.1 (Impacts from Explosives and Weapons Firing Noise) in the 2015 MITT Final EIS/OEIS. Impacts from aircraft noise are discussed in Section 3.10.3.1.2 (Impacts from Aircraft Noise) in the 2015 MITT Final EIS/OEIS. These sections discuss the different types of sounds, frequency ranges, and intensity generated from munitions use on FDM. Noise can result from direct munitions impacts (one object striking another), blasts (explosions that result in shock waves), bow shock waves (pressure waves from projectiles flying through the air), and substrate vibrations (combinations of explosion, recoil, or vehicle motion with the ground). Noise may be continuous, lasting for a long time without interruption, or impulsive, lasting for only a short duration. Continuous impulses (e.g., helicopter rotor noise, bursts from rapid-fire weapons) represent an intermediate type of sound and, when repeated rapidly, may resemble continuous noise. These types of sounds are distinguished here as they differ in their effects. Continuous and impulsive sounds can result in hearing damage, while shorter duration, less frequent, or lower sound levels typically elicit physiological or behavioral responses. Some birds may be killed or injured during these activities, or expend energy stores needed for migration to avoid or reduce perturbations generated by explosions.

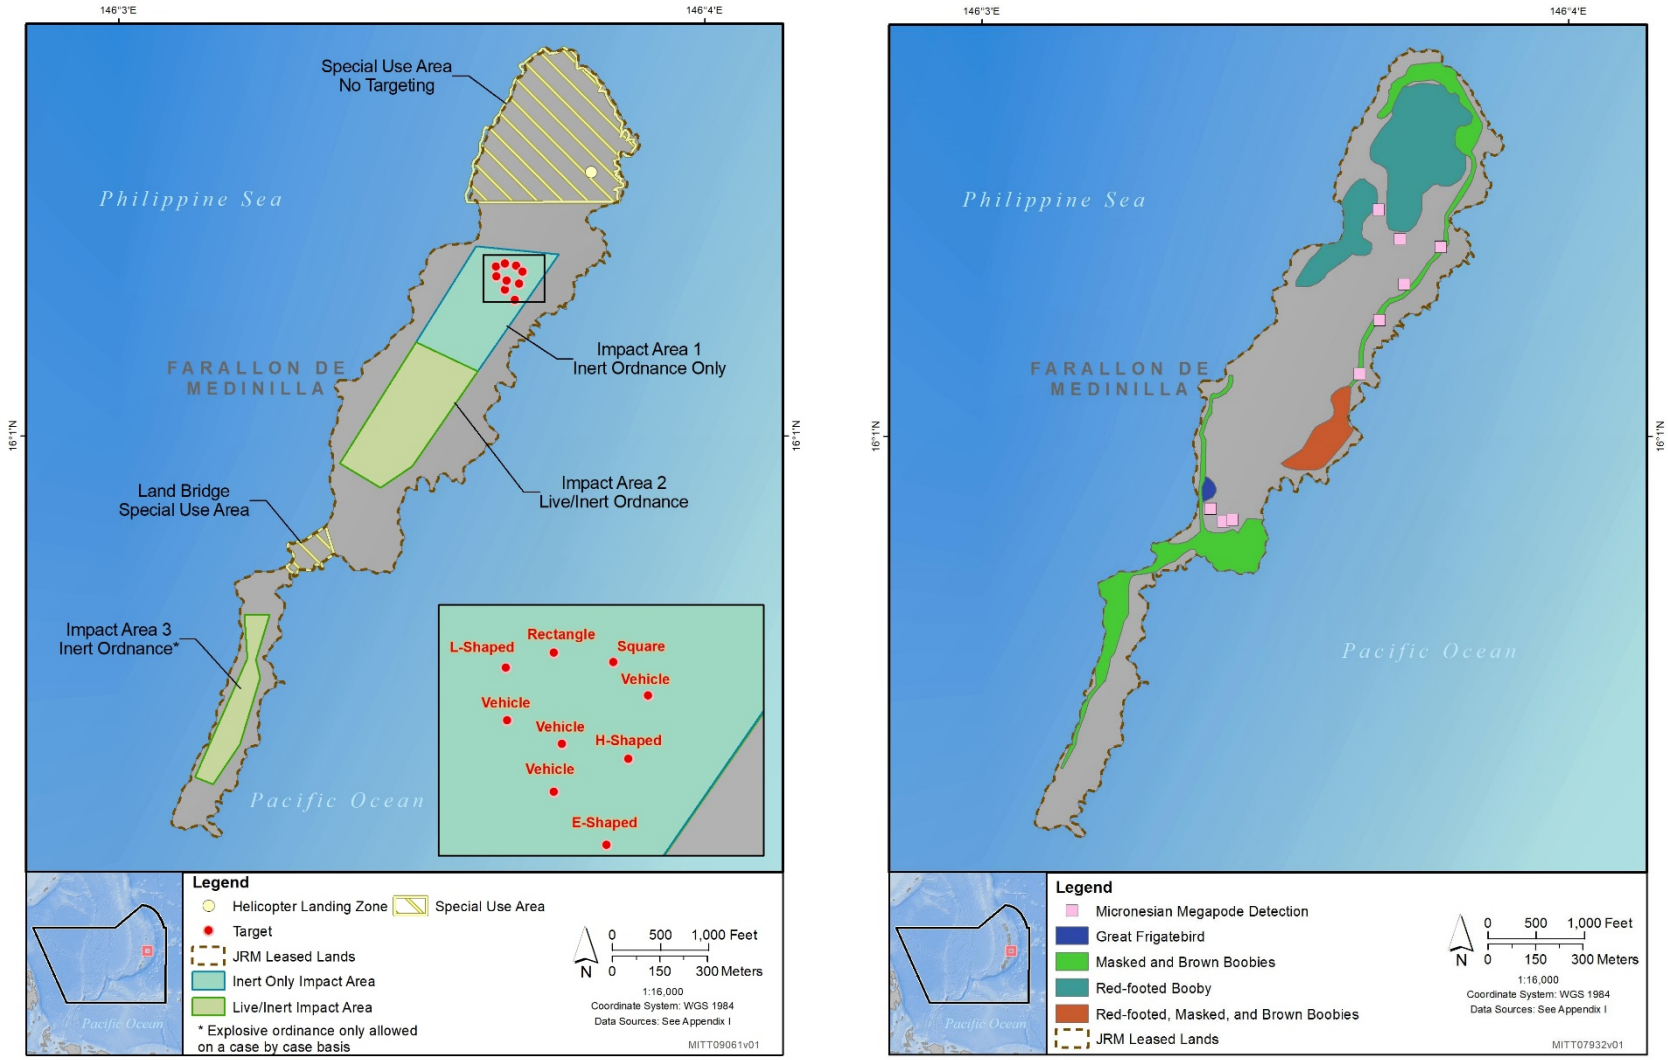
FDM has three impact areas, a special use area on the northern portion of the island, and a special use area on the land bridge. Targeting of areas inside of the special use areas and other areas outside of impact areas are prohibited. In other words, all areas outside of the impact areas are considered "no-fire areas." Any ordnance that inadvertently lands outside of impact areas, including special use areas and in water, must be reported to MIRC Operations, in accordance with Commander, U.S. Naval Forces

Marianas Instruction 3500.4A (U.S. Department of the Navy, 2011). The impact areas and special use areas are shown on Figure 3.10-1 and described below:

- **Northern Special Use Area**. Reserved for direct action (tactical air control party) type exercises and personnel recovery. This area is about 41 acres (ac.) (17 hectares [ha]) and includes a landing zone. Weapons may be fired from the special use area into impact areas, such as small-caliber rounds, grenades, and mortars.
- **Impact Area 1**. This area contains high-fidelity target structures and is comprised of vehicle shells and cargo containers. This area is authorized for inert ordnance only, and operators are required to report any live ordnance inadvertently dropped into Impact Area 1 to MIRC Operations. Impact Area 1 contains 10 targets of varying shapes and sizes, including 4 vehicles and 6 targets comprised of shipping containers.
- **Impact Area 2**. Impact Area 2 may be used for both live and inert ordnance. Strafing is permitted in this area. Impact Area 2 is about 22 ac. (9 ha).
- **Land Bridge**. The land bridge is designated as a "no target zone." Operators are required to report ordnance observed impacting the land bridge.
- **Impact Area 3**. This area is south of the land bridge and authorized for inert ordnance, although live ordnance may be used only with prior approval from Joint Region Marianas. Strafing is permitted in this area. Impact Area 3 is about 11 ac. (4.5 ha).

3.10.2.1.1 Impacts from Acoustic Stressors Under Alternative 1

Under Alternative 1, there would be an overall increase in the number of training events and munitions used on the island, which would increase the number of exposures to explosives noise, weapons firing noise, and aircraft overflights to deliver munitions to the impact zones on FDM. The types of explosive munitions used on FDM include explosive bombs (less than or equal to 2,000 pounds [lb.]), missiles, rockets, explosive grenades and mortars, medium-caliber projectiles, and large-caliber projectiles. The calculations for the increases in the number of events proposed on FDM are shown in Table 3.6-1. Table 3.6-2 shows the calculations for the proposed increases in the number of explosive and non-explosive munitions expended on FDM. These increases in events and munitions would result in an increase in net explosive weight (NEW) of explosives over the course of a training year. The calculations for NEW expended on FDM resulting from proposed training activities are shown in Table 3.6-3. The NEW for each ordnance type may vary within each class. Based on these NEW ranges within each explosives bin, the Navy calculated the range of total munitions' NEW under each alternative proposed in this SEIS/OEIS by multiplying the number of munitions used by the low and high NEW ranges for each ordnance type. Based on these calculations, the following assumptions are presented as additional analysis for this SEIS/OEIS:



- In terms of the number of events, there would be an increase of less than 2 percent over what was analyzed previously in the 2015 MITT Final EIS/OEIS. No new activity types are proposed in this SEIS/OEIS from what were previously analyzed in the 2015 MITT Final EIS/OEIS. Some activity types, however, would increase in the number of events per year and/or the number of ordnance items expended. Other activities would not change compared to what was analyzed previously in the 2015 MITT Final EIS/OEIS, and therefore would not contribute to an increase in NEW or the number of munitions expended on FDM. For example, Bombing Exercise (Air-to-Ground) is the most impactful in terms of explosive power released on FDM and would not increase compared to what was analyzed in the 2015 MITT Final EIS/OEIS. Table 3.6-1 shows

the number of events that would occur under each alternative compared to what was analyzed in the 2015 MITT Final EIS/OEIS.

- In terms of munitions item numbers, there would be an increase of approximately 9 percent over what was analyzed previously in the 2015 MITT Final EIS/OEIS in the total number of munitions used on FDM. Most of these increases are associated with small-caliber rounds, which do not contribute to increases in NEW. Table 3.6-2 shows the number of munitions proposed under each alternative compared to what was analyzed in the 2015 MITT Final EIS/OEIS.
- In terms of NEW, explosives used on FDM would increase by less than 1 percent compared to what was analyzed in the 2015 MITT Final EIS/OEIS (see calculations in Table 3.6-3).

Sources of noise from weapons firing that may be heard by wildlife on FDM (including the ESA-listed Micronesian megapode and Mariana fruit bat, bird species protected under the MBTA, and other native terrestrial wildlife assessed in the 2015 MITT Final EIS/OEIS) include close-in weapons firing from vessels, helicopters, close-combat surface firing from fixed-wing aircraft, and surface firing, with the largest increase in munitions use resulting from small arms, medium-caliber explosives, and mortar and grenade use during Direct Action training activities. As shown in Table 3.6-1, the number of training events (that involve weapon firing on or proximate to FDM) would stay the same compared to what was previously analyzed in the 2015 MITT Final EIS/OEIS; however, the number of munitions used would increase during each training event (see Table 3.6-2). These training events would occur within the Northern Special Use Area and fire into the impact areas towards the south; therefore, more megapodes and bats (along with other wildlife species) would be exposed to more weapons firing noise under Alternative 1 because of the increased number of small-caliber rounds, medium-caliber explosives, and grenades and mortars fired into impact areas from the Northern Special Use Area. The weapons-firing noise would likely be masked somewhat by natural sounds on FDM, such as waves and winds. The impulsive sound caused by weapon firings would have limited potential to mask any important biological sound simply because the duration of the impulse is brief, even when multiple shots are fired in series.

Although more ordnance may be used on FDM under Alternative 1 compared to what was analyzed previously in the 2015 MITT Final EIS/OEIS, all of the ordnance would be targeted at impact zones, with the same mitigation measures in place (discussed above in Section 3.10.2.1, Acoustic Stressors; and Chapter 5, Mitigation), and there would be no changes in how activities are performed compared to the previous analysis in 2015. For FDM's terrestrial biological resources, including ESA-listed species (the Micronesian megapode and Mariana fruit bat), bird species protected under the MBTA, and other native terrestrial plants and wildlife assessed in the 2015 MITT Final EIS/OEIS, the relatively small increase in annual NEW, numbers of ordnance expended, and the number of activities on FDM would not result in an appreciable change in the impact conclusions presented in the 2015 MITT Final EIS/OEIS for the following two reasons: (1) the increase in the amount of NEW (less than 1 percent increase), number of items expended (less than 10 percent increase), and the number of activities (less than 2 percent increase) would be minor when comparing Alternative 1 to NEW amounts analyzed in the 2015 MITT Final EIS/OEIS); and (2) the Navy would continue to implement the same avoidance and minimization measures in place as with the 2015 MITT Final EIS/OEIS (see Section 5.5, Terrestrial Mitigation Measures to be Implemented; and Table 5.5-1).

Note: Target locations in Impact Area 1 may change depending on target maintenance and training requirements.

Figure 3.10-1: Farallon de Medinilla Impact Zones and Micronesian Megapode Occurrences

The USFWS's 2015 Biological Opinion provided the Navy with an incidental take statement for the Mariana fruit bat and the Micronesian megapode (U.S. Fish and Wildlife Service, 2015). The Mariana fruit bat would not likely occur in impact zones and, if present on FDM, would likely be confined to the remnant tree cover at the northern end of the island. In the USFWS's 2015 Biological Opinion, one Mariana fruit bat was estimated to be killed over the course of five years as a result of bombing, gunnery, and missile exercises proposed in the 2015 MITT Final EIS/OEIS. The likelihood of increased exposure is negligible because of the small increases in the number of events, munitions, and NEW expended on FDM compared to what was analyzed in the 2015 MITT Final EIS/OEIS and 2015 USFWS Biological Opinion. In addition, the same avoidance and minimization measures in place included in the 2015 MITT Final EIS/OEIS and 2015 USFWS Biological Opinion would continue under Alternative 1 (see Section 5.5, Terrestrial Mitigation Measures to be Implemented; and Table 5-20).

In the USFWS's 2015 Biological Opinion, four Micronesian megapodes per year were estimated to be killed as a result of bombing, gunnery, and missile exercises proposed in the 2015 MITT Final EIS/OEIS. Based on the habitat conditions that persist within the impact zones, it is unlikely that additional megapodes would be exposed to additional ordnance use when used in the same locations previously analyzed. In summary, as the neither the Mariana fruit bat nor the Micronesian megapode will face increased exposure from the proposed additional ordnance to be expended, the incidental take statement provided to the Navy in 2015 as part of the USFWS's Biological Opinion is sufficient to cover potential impacts on ESA-listed species from activities proposed under Alternative 1 of this SEIS/OEIS.

Pursuant to the ESA, acoustic stressors during training activities on FDM, as described under Alternative 1, may affect the Micronesian megapode and the Mariana fruit bat. This determination is consistent with the previous consultation between the Navy and USFWS for activities described in the 2015 MITT Final EIS/OEIS. Because of the small increases in the amount of NEW used on FDM, the number of ordnance items expended, and the number of events that would occur on FDM under Alternative 1 compared to what was analyzed in the 2015 MITT Final EIS/OEIS, the activities proposed under Alternative 1 do not constitute a modification of the original proposed activities that causes new or additional effects on ESA-listed species on FDM; therefore, reinitiation of Section 7 consultation between the USFWS and Navy is not necessary.

Under the MBTA regulations applicable to military readiness activities (50 Code of Federal Regulations [CFR] Part 21), acoustic stressors on land during training activities under Alternative 1 would not result in significant adverse effects on terrestrial bird populations.

3.10.2.1.2 Impacts from Acoustic Stressors Under Alternative 2 (Preferred Alternative)

Under Alternative 2, the number of proposed training activities using explosive munitions would be similar as compared to Alternative 1, with an increase in the number of Direct Action events under Alternative 2 (compared to Alternative 1, see Table 3.6-1). The number of training events for this activity type would stay the same compared to what was previously analyzed in the 2015 MITT Final EIS/OEIS and under Alternative 1; however, the number of munitions used would increase during each training event under Alterative 2 (see Table 3.6-2). As with Alternative 1, these training events would occur within the Northern Special Use Area and fire into the impact areas towards the south; therefore, more megapodes and bats (along with other wildlife species) would be exposed to more weapons firing noise under Alternative 2 because of the increased number of small-caliber rounds, medium-caliber explosives, and grenades and mortars fired into impact areas from the Northern Special Use Area. The weapons-firing noise would likely be masked somewhat by natural sounds on FDM, such as waves and

winds. The impulsive sound caused by weapon firings would have limited potential to mask any important biological sound simply because the duration of the impulse is brief, even when multiple shots are fired in series. In addition, the same avoidance and minimization measures in place included in the 2015 MITT Final EIS/OEIS would continue under Alternative 2 (see Section 5.5, Terrestrial Mitigation Measures to be Implemented; and Table 5-20).

Therefore, the same conclusions for Alternative 1 for terrestrial biological resources, including the Micronesian megapode, Mariana fruit bat, and MBTA-protected terrestrial bird species, are applicable to Alternative 2.

Pursuant to the ESA, acoustic stressors during training activities on FDM, as described under Alternative 2, may affect the Micronesian megapode and the Mariana fruit bat. This determination is consistent with the previous consultation between the Navy and USFWS for activities described in the 2015 MITT Final EIS/OEIS. Because of the small increases in the amount of NEW used on FDM, the number of ordnance items expended, and the number of events that would occur on FDM under Alternative 2 compared to what was analyzed in the 2015 MITT Final EIS/OEIS, the activities proposed under Alternative 2 do not constitute a modification of the original proposed activities that causes new or additional effects on ESA-listed species on FDM; therefore, reinitiation of Section 7 consultation between the USFWS and Navy is not necessary.

Under the MBTA regulations applicable to military readiness activities (50 CFR Part 21), acoustic stressors on land during training activities under Alternative 2 would not result in significant adverse effects on terrestrial bird populations.

3.10.2.1.3 Impacts from Acoustic Stressors Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. For FDM, the lease agreement between the U.S. government and the Commonwealth of the Northern Mariana Islands would remain in place, and the island would continue to be maintained as a Navy range, although strike warfare would no longer continue on the island.

Acoustic stressors associated with Navy training activities would no longer be introduced to the island, which would minimize adverse noise impacts on FDM, such as disturbance of nesting and roosting birds and bats, sound pressure waves that may induce injury to wildlife, and adverse impacts associated with military noise on wildlife species at various life stages.

3.10.2.2 Explosives Stressors

The training activities that have the greatest impact on vegetation and wildlife communities within the impact areas on FDM are those that result in percussive force from the use of explosive munitions. The potential impacts of activities with these types of disturbances are discussed in Section 3.10.3.1.1 (Impacts from Explosives and Weapons Firing Noise) of the 2015 MITT Final EIS/OEIS.

3.10.2.2.1 Impacts from Explosive Stressors Under Alternative 1

As stated above in Section 3.10.2.1.1 (Impacts from Acoustic Stressors Under Alternative 1), there would be a small increase in the number of explosions on FDM, which would increase the number of exposures to percussive force. The types of explosive munitions used on FDM include explosive bombs (less than or equal to 2,000 lb.), missiles, rockets, explosive grenades and mortars, medium-caliber projectiles, and large-caliber projectiles. The number of explosive bombs (less than or equal to 2,000 lb.) would not

change compared to what was analyzed in the 2015 MITT Final EIS/OEIS, while the increases in NEW would be from the increased number of smaller NEW munitions (see Table 3.6-2). The total change in explosives use on FDM, in terms of NEW, would increase by less than 1 percent under Alternative 1 compared to what was analyzed in the 2015 MITT Final EIS/OEIS. Although more ordnance would be used on FDM under Alternative 1, all of the ordnance would target impact zones, with the same avoidance and minimization measures in place (see Section 5.5, Terrestrial Mitigation Measures to be Implemented; and Table 5-20).

As discussed in Section 3.10.2.1.1 (Impacts from Acoustic Stressors Under Alternative 1), the USFWS's 2015 Biological Opinion provided the Navy with an incidental take statement for the Mariana fruit bat and the Micronesian megapode (U.S. Fish and Wildlife Service, 2015). The Mariana fruit bat would not likely occur in impact zones and, if present on FDM, would likely be confined to the remnant tree cover at the northern end of the island. In the USFWS's 2015 Biological Opinion, one Mariana fruit bat was estimated to be killed over the course of five years as a result of bombing, gunnery, and missile exercises proposed in the 2015 MITT Final EIS/OEIS. The likelihood of increased exposure is negligible because of the small increases in the number of events, munitions, and NEW expended on FDM compared to what was analyzed in the 2015 MITT Final EIS/OEIS and 2015 USFWS Biological Opinion. In addition, the same avoidance and minimization measures in place included in the 2015 MITT Final EIS/OEIS and 2015 USFWS Biological Opinion would continue under Alternative 1 (see Section 5.5, Terrestrial Mitigation Measures to be Implemented; and Table 5-20). In the USFWS's 2015 Biological Opinion, four Micronesian megapodes per year were estimated to be killed as a result of bombing, gunnery, and missile exercises proposed in the 2015 MITT Final EIS/OEIS. Based on the habitat conditions that persist within the impact zones, it is unlikely that additional megapodes would be exposed to additional ordnance use when used in the same locations previously analyzed. In summary, as neither the Mariana fruit bat, nor the Micronesian megapode would face increased exposure from the proposed use of explosive ordnance, the incidental take statement provided to the Navy in 2015 as part of the USFWS's Biological Opinion is sufficient to cover potential impacts on ESA-listed species from activities proposed under Alternative 1 of this SEIS/OEIS.

Pursuant to the ESA, explosives stressors during training activities on FDM, as described under Alternative 1, may affect the Micronesian megapode and the Mariana fruit bat. This determination is consistent with the previous consultation between the Navy and USFWS for activities described in the 2015 MITT Final EIS/OEIS. Because of the small increases in the amount of NEW used on FDM, the number of ordnance items expended, and the number of events that would occur on FDM under Alternative 1 compared to what was analyzed in the 2015 MITT Final EIS/OEIS, the activities proposed under Alternative 1 do not constitute a modification of the original proposed activities that causes new or additional effects on ESA-listed species on FDM; therefore, reinitiation of Section 7 consultation between the USFWS and Navy is not necessary.

Under the MBTA regulations applicable to military readiness activities (50 CFR Part 21), explosions and weapons firing on land during training activities under Alternative 1 would not result in significant adverse effects on terrestrial bird populations.

3.10.2.2.2 Impacts from Explosive Stressors Under Alternative 2 (Preferred Alternative)

Under Alternative 2, there would be an increase in the number of events using FDM as a training location or target (see Table 3.6-1), with an increase in the number of munitions items expended on

FDM (see Table 3.6-2) compared to what was analyzed previously in the 2015 MITT Final EIS/OEIS and under Alternative 1.

Taken together, the increase in the number of events per year or the amount of ordnance used during events would result in an increase in the amount of NEW expended on FDM each year (see Table 3.6-3). Under Alternative 2, Naval Surface Firing Exercise events would expend more large-caliber projectiles, thereby slightly increasing the NEW expended under Alternative 2 compared to Alternative 1. Factors that limit the potential for additional adverse impacts, however, include maintaining the same ordnance type and targeting restrictions included as part of the 2015 MITT Final EIS/OEIS. Total NEW expended annually will continue to be limited by the terms of the 2015 USFWS BO. All ordnance expended on FDM would target existing impact zones, with the same ordnance restrictions imposed on all FDM activities and with the same avoidance and minimization measures in place (see Section 5.5, Terrestrial Mitigation Measures to be Implemented; and Table 5-20). As with Alternative 1, the likelihood of increased exposure under Alternative 2 is negligible because of the small increases in the number of events, munitions, and NEW expended on FDM compared to what was analyzed in the 2015 MITT Final EIS/OEIS and 2015 USFWS Biological Opinion. Therefore, the conclusions for terrestrial biological resources (including ESA-listed species and species protected by the MBTA) included in the 2015 MITT Final EIS/OEIS remain valid.

Pursuant to the ESA, explosive stressors during training activities on FDM, as described under Alternative 2, may affect the Micronesian megapode and the Mariana fruit bat. This determination is consistent with the previous consultation between the Navy and USFWS for activities described in the 2015 MITT Final EIS/OEIS. Because of the small increases in the amount of NEW used on FDM, the number of ordnance items expended, and the number of events that would occur on FDM under Alternative 2 compared to what was analyzed in the 2015 MITT Final EIS/OEIS, the activities proposed under Alternative 2 do not constitute a modification of the original proposed activities that causes new or additional effects on ESA-listed species on FDM; therefore, reinitiation of Section 7 consultation between the USFWS and Navy is not necessary.

Under the MBTA regulations applicable to military readiness activities (50 CFR Part 21), explosions and weapons firing on land during training activities under Alternative 2 would not result in significant adverse effects on terrestrial bird populations.

3.10.2.2.3 Impacts from Explosive Stressors Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. For FDM, the lease agreement between the U.S. government and the Commonwealth of the Northern Mariana Islands would remain in place, and the island would continue to be maintained as a Navy range, although strike warfare would no longer continue on the island.

Explosions associated with Navy training activities would no longer occur on the island, which would minimize adverse impacts associated with blast effects.

3.10.2.3 Physical Disturbance and Strike Stressors

The 2015 MITT Final EIS/OEIS analyzed the potential for physical disturbance and strike stressors, defined as including (1) direct strike, (2) habitat disturbance, (3) and the potential for wildfires. As discussed in Section 3.10.3.2 (Physical Stressors) in the 2015 MITT Final EIS/OEIS, the potential for impacts on vegetation communities and wildlife resources, including the Micronesian megapode,

Mariana fruit bats that may occur on the island, and land bird species, associated with direct strike from inert munitions is considerably lower than the potential for blast effects associated with explosive munitions.

Direct Action training activities require helicopter landings on FDM at a landing zone within the "no target area" (see Appendix A, Training and Testing Activities Descriptions, for a description of Direct Action training events). Marines and special warfare personnel would then disembark and conduct Direct Action training activities, where vegetation may be trampled. Because of unexploded ordnance clearance requirements, only marked trails (laid out by explosive ordnance disposal specialists prior to range clearance activities) are used, which reduces the potential for vegetation trampling (as well as nest trampling) in areas away from access trails.

Training activities that involve high explosive detonations on FDM introduce the potential for wildfires on the island. Cluster bombs, live cluster weapons, live scatterable munitions, fuel-air explosives, incendiary devices, and bombs greater than 2,000 lb. are prohibited on FDM. It should be noted that some munitions contain a small amount of phosphorous for spotting charges, and smoke markers are used in some direct action training activities. Phosphorous is not a main constituent to any munitions used on FDM. The live-fire weapons allowed are only targeted at impact areas authorized for live and inert ordnance. The areas for target placement support only low-growing vegetation because of long-term training with explosives. Dense vegetation grows on the northern portion of the island within the special use area, which could create a wildfire if weapons are misfired. Explosions may ignite fires in impact areas, which may spread to higher stature fine fuels outside of impact areas, endangering the remnant forest portions on the northern side of the island. However, the dense vegetation and shaded canopy of trees in the northern portion of the island likely increases the moisture content of vegetation, which should decrease the ability of fires to spread into the special use area.

3.10.2.3.1 Impacts from Physical Disturbance and Strike Stressors Under Alternative 1

Under Alternative 1, direct strike of individual birds and bats on FDM is unlikely because the increased activities (missile exercises and direct-action training activities) would occur within the impact zones already established on the island. These areas are highly degraded and do not support sufficient cover and forage resources to be considered high-value habitat on FDM. Therefore, the impact areas are not likely to attract terrestrial wildlife resources, and would attract few (if any) Micronesian megapodes and likely no Mariana fruit bats.

The small increase in explosions under Alternative 1 (see Table 3.6-3) compared to the amount analyzed in the 2015 MITT Final EIS/OEIS, as measured in terms of NEW, would unlikely be additive to wildfire risk on FDM. As described above, munitions use on FDM can ignite wildfires. Wildfire intensity may vary based on the amount and type of munitions, wind speed, levels of humidity, seasonal variation in vegetation thickness and composition, and successional state of vegetation. Micronesian megapodes on FDM would be expected to fly away from smoke, but exposure to smoke inhalation would result in some form of respiratory distress. Direct mortality of megapodes could result from intensive respiratory distress or encirclement of burning vegetation. Megapode eggs, even in burrows, would not likely survive a wildfire overburn on FDM. Likewise, any fledglings within a burn area would be expected to suffer intensive respiratory distress, as they would be unable to flee smoke or burning vegetation. As stated above, fires are unlikely to spread to the northern portion of FDM; the northern portion of the island would continue to serve as refugia for Micronesian megapodes that either reside in this area or for megapodes able to flee smoke and flames from target areas. Therefore, despite more explosions on

FDM, they would occur within the same impact zones, which reduces the potential for overburns in new previously unburned areas.

Pursuant to the ESA, physical disturbance and strike stressors during training activities on FDM, as described under Alternative 1, may affect the Micronesian megapode and the Mariana fruit bat. This determination is consistent with the previous consultation between the Navy and USFWS for activities described in the 2015 MITT Final EIS/OEIS. Because of the small increases in the amount of NEW used on FDM, the number of ordnance items expended, and the number of events that would occur on FDM under Alternative 1 compared to what was analyzed in the 2015 MITT Final EIS/OEIS, the activities proposed under Alternative 1 do not constitute a modification of the original proposed activities that causes new or additional effects on ESA-listed species on FDM; therefore, reinitiation of Section 7 consultation between the USFWS and Navy is not necessary.

Under the MBTA regulations applicable to military readiness activities (50 CFR Part 21), physical disturbance and strike stressors during training activities under Alternative 1 would not result in significant adverse effects on terrestrial bird populations.

3.10.2.3.2 Impacts from Physical Disturbance and Strike Stressors Under Alternative 2 (Preferred Alternative)

Under Alternative 2, there would be an increase in the number of events using FDM as a training location or target (see Table 3.6-1), with an increase in the number of munitions items expended on FDM (see Table 3.6-2) compared to what was analyzed previously in the 2015 MITT Final EIS/OEIS and under Alternative 1.

Taken together, the increase in the number of events per year or the amount of ordnance used during events would result in an increase in the amount of NEW expended on FDM each year (see Table 3.6-3). Although the amount of increased NEW is negligible, the potential exposure to stressors associated with ordnance use would increase under Alternative 2 compared to what was analyzed previously in the 2015 MITT Final EIS/OEIS. Under Alternative 2, Naval Surface Firing Exercise events would expend more large-caliber projectiles, thereby slightly increasing the NEW expended under Alternative 2 compared to Alternative 1. Factors that limit the potential for additional adverse impacts associated with physical disturbance and strike, however, include maintaining the same ordnance type and targeting restrictions included as part of the 2015 MITT Final EIS/OEIS. All ordnance expended on FDM would target existing impact zones, with the same ordnance restrictions imposed on all FDM activities and with the same avoidance and minimization measures in place (see Section 5.5, Terrestrial Mitigation Measures to be Implemented; and Table 5-20). Therefore, the increases in ordnance use on FDM shown in Tables 2.5-1 and 2.5-2 do not appreciably change the impact conclusions presented in the 2015 MITT Final EIS/OEIS. The conclusions for terrestrial biological resources (including ESA-listed species and species protected by the MBTA) included in the 2015 MITT Final EIS/OEIS remain valid.

Pursuant to the ESA, physical disturbance and strike stressors during training activities on FDM, as described under Alternative 2, may affect the Micronesian megapode and the Mariana fruit bat. This determination is consistent with the previous consultation between the Navy and USFWS for activities described in the 2015 MITT Final EIS/OEIS. Because of the small increases in the amount of NEW used on FDM, the number of ordnance items expended, and the number of activities that would occur on FDM under Alternative 2 compared to what was analyzed in the 2015 MITT Final EIS/OEIS, the activities proposed under Alternative 2 do not constitute a modification of the original proposed activities that causes new or additional effects on ESA-listed species on FDM; therefore, reinitiation of Section 7 consultation between the USFWS and Navy is not necessary.

Under the MBTA regulations applicable to military readiness activities (50 CFR Part 21), physical disturbance and strike stressors during training activities under Alternative 2 would not result in significant adverse effects on terrestrial bird populations.

3.10.2.3.3 Impacts from Physical Disturbance and Strike Stressors Under No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. For FDM, the lease agreement between the U.S. government and the Commonwealth of the Northern Mariana Islands would remain in place, and the island would continue to be maintained as a Navy range, although strike warfare would no longer continue on the island.

Explosions associated with Navy training activities would no longer occur on the island, which would minimize adverse impacts associated with physical disturbance and strike stressors.

3.10.2.4 Secondary Stressors

The 2015 MITT Final EIS/OEIS included an analysis of the potential impacts of secondary stressors on terrestrial species and habitats. Specifically, this section addresses the potential introduction of invasive species. Section 3.10.3.3.1 (Impacts from Invasive Species Introductions) in the 2015 MITT Final EIS/OEIS discusses potential introduction pathways of invasive species associated with training activities described in this SEIS/OEIS.

The 2015 MITT Final EIS/OEIS included a conceptual model of invasive species pathways (Figure 3.10-10 in the 2015 MITT Final EIS/OEIS) resulting from training activities, and specific invasive species interdiction measures that avoid or minimize risk of specific pathways (see Table 3.10-7 in the 2015 MITT Final EIS/OEIS). Of the two training activity types that would increase on FDM under Alternative 1, only Direct Action training activities present potential introduction pathways for invasive species. Introduction pathways that originate on Guam and end on FDM present a potential hazard for brown treesnake dispersal. For activities described in this SEIS/OEIS, potential introduction pathways would be associated with helicopter transports to FDM. The Brown Tree Snake Control and Interdiction Requirements are included in the Commander, U.S. Naval Forces Marianas Instruction 3500.4A (dated October 8, 2013). This document describes roles and responsibilities for exercise planners to interdict and control brown treesnakes and to disseminate information to participants throughout the chain of command. Other policies and instructions associated with military training activities and potential invasive species introductions include Office of the Chief of Naval Operations Instruction 5090.1D (updated in 2013) and Armed Forces Pest Management Board Technical Guide 31 (Armed Forces Pest Management Board, 2012). For instance, any personnel involved in training activities on FDM conduct self inspections to avoid or reduce potential introductions of invasive species from points of origin to FDM. Points of origin include Guam and Saipan, and possibly Tinian. Personnel inspect all gear and

clothing (e.g., boots, bags, weapons, and pants) for soil accumulations, seeds, invertebrates, and possible inconspicuous stowaway brown treesnakes).

The Direct Action training activities, which are proposed to increase, would still be subject to biosecurity measures. The potential introduction of invasive species to FDM from additional transits to FDM during Direct Action training activities is unlikely; therefore, there would be no appreciable increase in risk from activities analyzed in the 2015 MITT Final EIS/OEIS.

With the small increase (less than 1 percent) in the amount of NEW used on FDM under Alternative 1 and Alternative 2 compared to what was analyzed in the 2015 MITT Final EIS/OEIS, the activities proposed in this SEIS do not constitute a modification of the original proposed activities that causes new or additional effects from secondary stressors on ESA-listed species on FDM; therefore, reinitiation of Section 7 consultation between the USFWS and Navy is not necessary.

3.10.3 Public Comments

The public raised a number of issues during the scoping period in regard to terrestrial species and habitats. The issues are summarized in the list below. Comments received from the public during the Draft SEIS/OEIS commenting period related to terrestrial species and habitats are addressed in Appendix K (Public Comment Responses).

- **Public comments concerning a lack of studies on FDM** – Some commenters noted a lack of studies documenting the condition of terrestrial biological resources on FDM. Complete natural resource inventories on the island are subject to a number of constraints, such as safety concerns regarding unexploded ordnance and scheduling surveys to avoid both training activities and weather. Surveys are conducted on a periodic basis on FDM. On-the-ground surveys are conducted primarily to monitor Micronesian megapodes on the island. These surveys are described in more detail in Section 3.10.2.3.8.4 (Status within the Mariana Islands Training and Testing Study Area) in the 2015 MITT Final EIS/OEIS. Aerial surveys are conducted more frequently over FDM, with the primary focus on monitoring seabird rookeries (primarily brown boobies, masked boobies, and red-footed boobies). These surveys are described in more detail, along with quantitative trend analysis of populations, in Section 3.6.2 (Farallon de Medinilla) of the 2015 MITT Final EIS/OEIS. All of these studies are summarized and included in updates to the Joint Region Marianas Integrated Natural Resources Management Plan for Joint Region Marianas-administered and Leased Lands On Guam, Tinian, and FDM (U.S. Department of the Navy, 2019), which is shared with cooperating agencies (e.g., Guam Department of Agriculture Division of Aquatic and Wildlife Resources, Commonwealth of Northern Mariana Islands Department of Land and Natural Resources Division of Fish and Wildlife, and USFWS Pacific Islands Fish and Wildlife Office).
- **Potential impacts on vegetation communities on FDM –** One comment raised the concern of vegetation loss resulting from bombing activities at FDM. Vegetation loss over the long term is described in Section 3.10.2.1.5 (Farallon de Medinilla) in the 2015 MITT Final EIS/OEIS. Few vegetation surveys have been conducted on FDM. The first published flora record in 1902, described the island as a plateau covered by brush approximately 13 feet (4.0 meters) high (Mueller-Dombois & Fosberg, 1998); however, aerial photographs from 1944 show large canopy trees on FDM (see Figure 3.10-4 in the 2015 MITT Final EIS/OEIS). FDM's vegetation appears to have undergone significant changes since the island was leased by the Department of Defense and the subsequent bombardment for military training. The most intensive bombardment to

date of FDM occurred during the Vietnam era, when as much as 22 tons of ordnance per month was dropped on the island (Lusk et al., 2000). Based on early 20th century descriptions of FDM vegetation and aerial photographs of the island prior to military bombardment activities, island tree height and canopy cover have been greatly reduced (Lusk et al., 2000; Mueller-Dombois & Fosberg, 1998). The avoidance and minimization measures currently implemented on FDM, as described in the 2015 MITT Final EIS/OEIS and Chapter 5 (Mitigation) of this SEIS/OEIS, are designed to protect the area of the island occupied by the Micronesian megapode in the "No Drop Zone." According to Lusk et al. (2000), vegetation in this area has not substantially changed since 1974. The USFWS, in their Biological Opinion signed in 2015 for activities described in the 2015 MITT Final EIS/OEIS, suggests that the avoidance and minimization measures have protected species and habitats in the northern portion of the island (U.S. Fish and Wildlife Service, 2015), while the reductions in vegetation structure and composition have occurred in designated impact zones to the south of the "No Drop Zone." In summary, the Navy concurs that there have been significant losses of vegetation on FDM resulting from military training activities. Mitigation measures that have been designed in cooperation with USFWS personnel provide a level of protection for the northern end of the island, while ordnance use is only allowed in designated impact zones. Increases in ordnance use on FDM would only occur in existing impact zones, causing no new additional vegetation losses on the island.

3.11 Cultural Resources

3.11.1 Affected Environment

This section supplements the analysis of impacts on cultural resources presented in the 2015 Mariana Islands Training and Testing (MITT) Final Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS). New information made available since the publication of the 2015 MITT Final EIS/OEIS is included below to better understand potential stressors and impacts on cultural resources resulting from training and testing activities. Information presented in the 2015 MITT Final EIS/OEIS that remains valid is noted as such and referenced in the appropriate sections. Comments received from the public during scoping related to cultural resources are addressed in Section 3.11.3 (Public Comments). Comments received from the public during the Draft Supplemental EIS (SEIS)/OEIS commenting period related to cultural resources are addressed in Appendix K (Public Comment Responses).

A 10-year programmatic agreement (PA) that addressed potential effects to historic properties in the Mariana Islands Range Complex (MIRC) study area expired in December 2019. The PA provided the Department of Defense with compliance under the National Historic Preservation Act (NHPA). This process is separate and distinct from the Navy's responsibilities under the National Environmental Policy Act. However, as the need for a new PA was concurrent with the development of this MITT SEIS/OEIS, the Navy conducted Section 106 consultation in conjunction with the National Environmental Policy Act process. This benefitted both processes as comments received through the consultation process have been incorporated into this SEIS/OEIS, and vice versa.

3.11.1.1 Guam, Mariana Islands

Following a review of recent literature, no additional submerged cultural resources have been identified around Guam. However, geospatial data provided by the National Oceanographic and Atmospheric Administration (NOAA) documented the presence of several wrecks, obstructions, or occurrences in the waters around Guam (Lord et al., 2003) (**Error! Reference source not found.**). These submerged cultural resources have not been formally evaluated as historic properties eligible for listing in National Register of Historic Places. (see Section 3.11.1.1, Identification, Evaluation, and Treatment of Cultural Resources of the 2015 MITT Final EIS/OEIS for an explanation of the procedures associated with cultural resources); however, they will be treated as if they were eligible

3.11.1.2 Commonwealth of the Northern Mariana Islands

3.11.1.2.1 Farallon de Medinilla

Following a literature review, no additional submerged cultural resources, land-based archaeological sites, or isolated non-modern artifacts have been identified around or on Farallon de Medinilla (FDM). A reconnaissance archaeological field survey on FDM was conducted in 1996 (Welch, 1997). No archaeological sites or isolated non-modern artifacts were observed; however, smoke-blackened caves and fragments (i.e., pottery sherds) were observed. Modern debris associated with the military use of the island was also observed. As such, the information presented in the 2015 MITT Final EIS/OEIS is still valid and the most current.

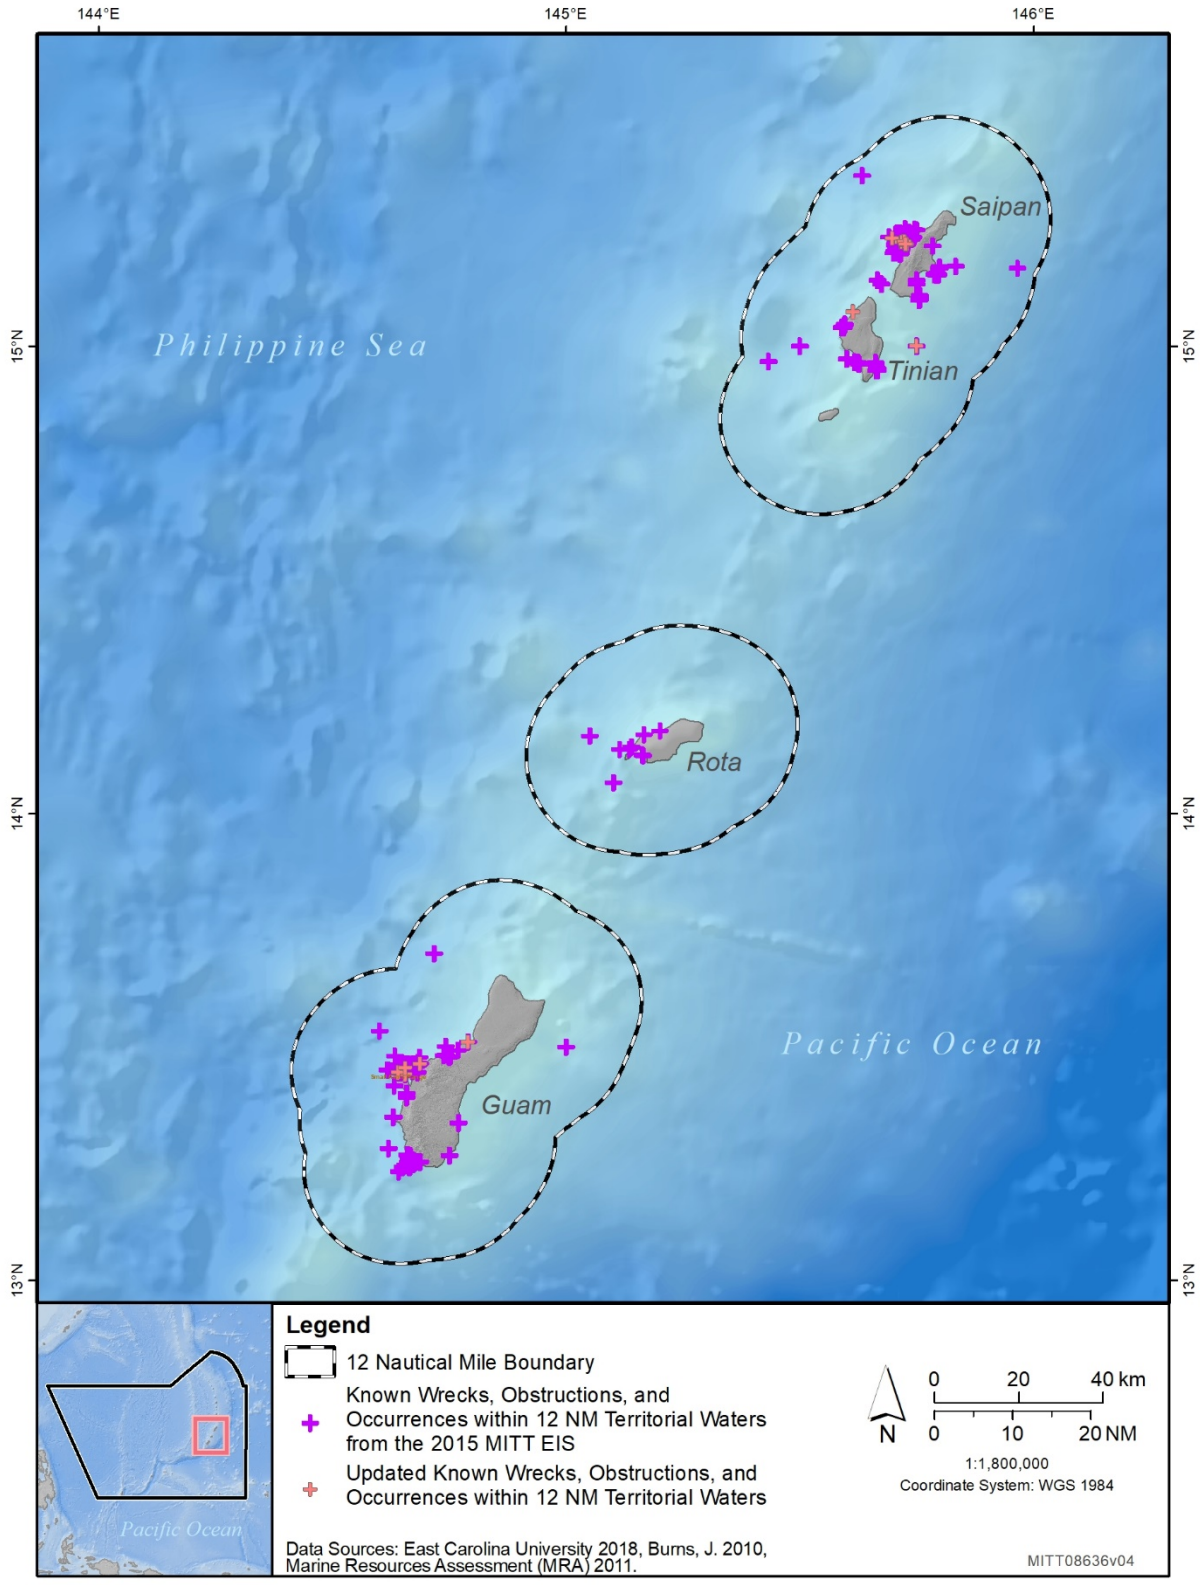

Figure 3.11-1: Known Wrecks, Obstructions, or Occurrences Within the United States Territorial Waters

3.11.1.2.2 Tinian

Following a literature review, additional submerged cultural resources have been identified around Tinian (**Error! Reference source not found.**). In 2017, East Carolina University partnered with the non-profit organization Ships of Exploration and Discovery on a National Parks Service America Battlefield Protection Program grant to conduct an archaeological investigation in the Commonwealth of the Northern Mariana Islands (CNMI). A portion of the 2017 project was dedicated to examining Tinian's World War II invasion beaches Unai Babui and Unai Chulu. The 2017 study was a follow-up study on the original American Battlefield Protection Program grant and a 2010 study of the nearshore areas, which identified potential anomalies in the nearshore areas of Unai Chulu (Burns, 2010). Researchers discovered two previously unidentified cultural resources within the Study Area landing beaches of Tinian: an intact World War II Danforth anchor and a previously unknown, fairly intact Landing Vehicle Tracked-2 in approximately 45 feet (ft.) of water (McKinnon et al., 2017). Researchers also discovered portions of a second Landing Vehicle Tracked, a large stockless U.S. Navy anchor, and a tire that may belong to a DUCKW, a six-wheel-drive amphibious modification of the CCKW trucks (2.5-ton truck) used during World War II in approximately 20 ft. of water in the nearshore area of Unai Babui.

Geospatial data provided by NOAA also documented the presence of several wrecks, obstructions, or occurrences in the waters around Tinian (Lord et al., 2003). The submerged cultural resources have not been formally evaluated for eligibility for inclusion in the National Register of Historic Places; however, they will be treated as if they were eligible.

3.11.1.2.3 Saipan

Following a literature review, one additional submerged cultural resource has been identified around Saipan. The results of an underwater archaeological survey conducted in 2011 and published in 2016 describe a mid-to-late 19th-century wooden ship found in Tanapag Lagoon on the western side of Saipan, along with artifacts and an associated debris field. While the study confirmed the shipwreck to be from the colonial period prior to World War II, it was inconclusive as to the positive identity of the ship (McKinnon et al., 2016). In addition, geospatial data provided by NOAA documented the presence of several wrecks, obstructions, or occurrences in the waters around Saipan (Lord et al., 2003) (Figure 3.11-1). These submerged cultural resources have not been formally evaluated as historic properties eligible for listing in the National Register of Historic Places; however, they will be treated as if they were eligible.

3.11.1.2.4 Rota

Following a literature review, no additional submerged cultural resources have been identified around Rota. As such, the information presented in the 2015 MITT Final EIS/OEIS is still valid and the most current.

3.11.1.3 Cultural/Traditional Practices and Beliefs

Chamorros and Carolinians have a unique cultural history in the Marianas, with which they are closely connected. As far back as 4,000 years ago, the Chamorros migrated from Southeast Asia to the Mariana Islands. Their people and culture experienced centuries of change, from Spanish occupation in the 16th and 17th centuries, to European-introduced diseases and conflict over land in the 18th century, to Japanese occupation during World War II. To present day, Chamorros and Carolinians strive to maintain their ancestral heritage, cultural traditions, and language.

A number of public comments on the Draft SEIS/OEIS refer to the history of displacement and marginalization the Chamorros and Carolinians experienced, suggesting the Proposed Action represents a comparable impact on existing cultural practices. Commenters stated that military training and testing activities within the Mariana Islands are believed to hinder cultural beliefs, access to cultural sites, and the ability to practice cultural traditions. While specific practices were not described in the comments, cultural traditions include (but are not limited to) resource collection for traditional events or ceremonial purposes, seafaring customs, and practices related to traditional and familial roles.

3.11.1.4 Mariana Islands Training and Testing Transit Corridor

The length and variable width of the MITT transit corridor is so vast and deep (sometimes over 18,000 ft. [5,486 meters]), that it precludes systematic survey for submerged cultural resources. In accordance with the NHPA Section 402 regarding international federal activities affecting historic properties, the World Heritage List was reviewed, and no known natural/cultural resources were identified within the MITT transit corridor.

3.11.1.5 Current Requirements, Practices, and Protective Measures

3.11.1.5.1 Avoidance of Obstructions

As stated in the 2015 MITT Final EIS/OEIS, the military avoids locations of known obstructions, which includes submerged cultural resources such as historic shipwrecks. Known obstructions are avoided to prevent damage to sensitive equipment and vessels, for mission success, and to avoid or reduce potential impacts on cultural resources (Section 2.3.3, Standard Operating Procedures; and Chapter 5, Mitigation).

3.11.1.5.2 Mariana Islands Range Complex Programmatic Agreement

A Programmatic Agreement (PA) was negotiated in 2009 for all military training activities proposed in the MIRC. The PA was based on consultations with the Guam State Historic Preservation Officer (SHPO), CNMI Historic Preservation Officer (HPO), Advisory Council on Historic Preservation, and the National Park Service. The training constraints map identifies Limited Training zones, refined from the previous Military Operations Area constraints map boundaries (U.S. Department of Defense, 2009). Limited Training zones (land-based) are primarily designated as no digging, no vegetation clearing, and no campfire areas. Vehicular access is limited to designated roadways with the use of rubber-tired vehicles. While there are no limits on the quantity of personnel, training in Limited Training zones typically consist of units numbering 20 or fewer. Limited Training and Testing zones (at-sea) are designated for avoidance of historic properties or other environmentally sensitive areas. No Training zones are off limits to training and testing activities.

According to the 2009 PA, training constraint maps shall be reviewed by the Senior Military Official Cultural Resource Manager (CRM) and/or 36th Wing CRM on an annual basis to ensure the maps remain current and take into account any new surveys, studies, or inadvertent and post-review finds. Revisions to the maps shall be consulted upon with the Guam SHPO and CNMI HPO prior to finalization. Each review by the CRM and any resulting revision to the maps shall be reported.

The PA expired in December 2019, and the Navy efforts are ongoing to maintain compliance with the NHPA. Since January 2019, the Navy has been actively engaged in a new NHPA Section 106 consultation with the Guam and CNMI HPOs, consulting parties and members of the interested public. As it has been determined that MITT military readiness training has the potential to affect historic properties in the study area, the Navy is working to develop a MITT PA to maintain NHPA compliance. As we continue to

actively consult and develop a new long-term PA for the MITT undertaking, the Parties have executed interim PAs which incorporate all of the terms and mitigations of the 2009 PA. The interim PAs took effect upon the expiration of the 2009 MITT PA and serve as a continuation of the Department of Defense's compliance under Section 106 of the NHPA for MITT activities. The interim PA with the CNMI HPO expires September 10, 2020, while the interim PA with Guam expires June 30, 2020.

3.11.2 Environmental Consequences

The 2015 MITT Final EIS/OEIS considered training and testing activities proposed to occur in the Study Area that may have the potential to impact cultural resources. The stressors applicable to cultural resources in the Study Area are the same stressors in the 2015 MITT Final EIS/OEIS and include:

- explosive (in-water explosions), and
- physical disturbance and strike (ground disturbance, use of towed in-water devices, deposition of military expended materials, and use of seafloor devices).

This section evaluates how and to what degree potential impacts on cultural resources from stressors described in Section 3.0.1 (Overall Approach to Analysis) may have changed since the analysis presented in the 2015 MITT Final EIS/OEIS was completed. Tables 2.5-1 and 2.5-2 in Chapter 2 (Description of Proposed Action and Alternatives) list the proposed training and testing activities and include the number of times each activity would be conducted annually and the locations within the Study Area where the activity would typically occur under each alternative. The tables also present the same information for activities described in the 2015 MITT Final EIS/OEIS so that the proposed levels of training and testing under this SEIS/OEIS can be easily compared.

The Navy conducted a review of federal and state regulations and standards relevant to cultural resources and reviewed literature published since 2015 for new information on cultural resources (as presented in Section 3.11.1, Affected Environment) that could inform the analysis presented in the 2015 MITT Final EIS/OEIS. The analysis presented in this section also considers standard operating procedures, which are discussed in Section 2.3.3 (Standard Operating Procedures) of this SEIS/OEIS, and mitigation measures that are described in Chapter 5 (Mitigation). The Navy would implement these measures to avoid or reduce potential impacts on cultural resources from stressors associated with the proposed training and testing activities. Protective measures for cultural resources will be coordinated with the Guam SHPO, CNMI HPO Advisory Council on Historic Preservation, and the National Park Service as part of the Section 106 consultation process.

3.11.2.1 Explosive Stressors

Explosive stressors that have the potential to impact cultural resources are shock (pressure) waves and vibrations from underwater detonations (such as explosive torpedoes, missiles, bombs, projectiles, airguns, and mines) and cratering created by underwater explosions. While the number of training and testing activities would change under this SEIS/OEIS (refer to Tables 2.5-1 and 2.5-2), the locations of activities and the analysis presented in the 2015 MITT Final EIS/OEIS, Section 3.11.3.1.1 (Impacts from Explosives – Shock [Pressure] Waves from Underwater Explosions) and Section 3.11.3.1.2 (Impacts from Explosives – Cratering) remains valid.

3.11.2.1.1 Impacts from Explosive Stressors Under Alternative 1

Under Alternative 1, the annual number of explosive munitions expended at sea in the Study Area would decrease overall from the 2015 MITT Final EIS/OEIS. However, under this alternative, underwater detonation activities would increase for Limpet Mine Neutralization System and Underwater Demolition

Qualification/Certification above the 2015 MITT Final EIS/OEIS (Table 2.5-1 and Table 3.0-16). The explosive ordnance would continue to occur in the same areas and would have no appreciable change in the impact analysis or conclusions for explosive stressors as presented in the 2015 MITT Final EIS/OEIS.

As stated in the 2015 MITT Final EIS/OEIS analysis, training and testing activities using explosives would not typically occur within approximately 3 nautical miles from shore, including the nearshore waters surrounding Tinian, Saipan, or Rota. Therefore, no shock (pressure) waves, vibrations, or cratering from explosions would occur in these areas, and no known submerged cultural resources would be affected by explosive stressors. For those training activities at the Agat Bay Floating Mine Neutralization Site, Piti Point Floating Mine Neutralization Site, and Apra Harbor Underwater Demolition Site (located within Outer Apra Harbor), the military avoids locations of known obstructions, which includes submerged cultural resources (Section 2.3.3, Standard Operating Procedures; and Section 5.4.1, Mitigation Areas for Seafloor Resources). Thus, it is unlikely that cultural resources could be disturbed or destroyed from shock waves or cratering created by underwater explosions during mine warfare activities, surface warfare activities, torpedo testing, mine countermeasure mission package activities, or other training activities that use explosives.

In summary, given that the training and testing activities would decrease and be conducted in the same areas as described in the 2015 analysis, the amount of shock (pressure) waves, vibrations, or cratering from explosives would not appreciably change the conclusions. Therefore, the analysis presented in the 2015 MITT Final EIS/OEIS, Section 3.11.3.1.1 (Explosive Stressors – Shock (Pressure) Waves from Underwater Explosions) and Section 3.11.3.1.2 (Impacts from Explosives – Cratering) remains valid. Explosive stressors resulting from underwater explosions creating shock (pressure) waves, vibrations, and cratering of the seafloor would not adversely affect submerged cultural resources under Alternative 1 within U.S. territorial waters because measures have been previously implemented to protect these resources and would continue to be implemented according to the mitigation measures and procedures identified and described in the 2009 MIRC PA and the successor MITT PA documents or interim PAs.

3.11.2.1.2 Impacts from Explosive Stressors Under Alternative 2 (Preferred Alternative)

Under Alternative 2, the annual number of explosive munitions expended at sea in the Study Area would decrease overall from the 2015 MITT Final EIS/OEIS. However, under this alternative, underwater detonation activities would increase for Limpet Mine Neutralization System and Underwater Demolition Qualification/Certification above the 2015 MITT Final EIS/OEIS (Table 2.5.1 and Table 3.0-16). As noted under Alternative 1, the explosive ordnance would continue to occur in the same areas and would have no appreciable change in the impact analysis or conclusions for explosive stressors as summarized above under Alternative 1 and as presented in the 2015 MITT Final EIS/OEIS.

3.11.2.1.3 Impacts from Explosive Stressors Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Explosive stressors as listed above would not be introduced into the marine environment. Therefore, depending on other activities not related to the MITT undertaking, existing environmental conditions of submerged cultural resources would remain unchanged after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer explosive stressors within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential

for explosive impacts on submerged cultural resources, but would not measurably improve the condition of submerged cultural resources in the Study Area.

3.11.2.2 Physical Disturbance and Strike

The physical disturbance and strike stressors that may impact cultural resources include (1) vessels and towed in-water devices, (2) military expended materials, and (3) seafloor devices.

3.11.2.2.1 Impacts from Physical Disturbance and Strike Stressors Under Alternative 1

Under Alternative 1, the number of proposed training and testing events would increase for vessels, decrease for towed in-water devices, increase for non-explosive practice munitions, decrease for military expended materials, and decrease for seafloor devices (see Tables 3.0-12, 3.0-13, 3.0-14, 3.0-15, and 3.0-18, respectively) compared to the numbers in the 2015 MITT Final EIS/OEIS.

Proposed increases under Alternative 1 for vessels would have no appreciable change on the impact analysis or conclusions for physical disturbance and strike stressors presented in the 2015 MITT Final EIS/OEIS because the increase in training and testing events including the use of vessels is not substantial (Table 3.0-12). Thus, the analysis presented in the 2015 MITT Final EIS/OEIS, Section 3.11.3.2.2 (Impacts from Vessel and In-Water Device Strikes) remains valid.

As stated in the 2015 MITT Final EIS/OEIS, the impact of physical disturbance and strike stressors on cultural resources would be inconsequential for vessels and in-water devices because (1) the types of activities associated with towed systems are conducted in areas where the sea floor is deeper than the length of the tow lines; (2) prior to deploying a towed device, there is a standard operating procedure to search the intended path of the device for any floating debris (e.g., driftwood) or other potential surface obstructions, since they have the potential to cause damage to the device; and (3) devices are designed and operated within the water column and do not contact the seafloor. Activities involving vessels and in-water devices are not expected to affect submerged cultural resources.

The proposed increase under Alternative 1 in non-explosive practice munitions (Table 3.0-14) is attributed to the increase in small-caliber projectiles. Larger non-explosive practice munitions such as torpedoes, bombs, and missiles would all decrease under Alternative 1. As stated in the 2015 MITT Final EIS/OEIS, the deposition of non-explosive practice munitions, sonobuoys, and military expended materials other than ordnance may affect submerged cultural resources through possible sudden impact of resources on the seafloor or the simple settling of military expended materials on top of submerged cultural resources. However, the impact of non-explosive practice munitions or military expended materials on cultural resources would be inconsequential because most of the anticipated expended munitions would be small objects and fragments that lose velocity after striking the ocean surface and drift to the seafloor. Larger and heavier objects, such as non-explosive practice munitions, would strike the ocean surface with greater velocity, but their acceleration would slow upon impact with the ocean surface. It is possible these larger and heavier objects could impact a submerged cultural resource site by creating sediment and artifact displacement. A historic resource could be impacted by damaging structural elements; the probability increases in areas where there is a higher density of resources. However, this type of impact is not anticipated because the Navy avoids areas with known submerged obstructions, including submerged objects and sites listed on the National Register of Historic Places. Thus, the increase in non-explosive practice munitions would have no appreciable change on the impact analysis or conclusions for physical disturbance and strike stressors presented in the 2015 MITT Final EIS/OEIS.

As stated in the 2015 MITT Final EIS/OEIS, any physical disturbance on the continental shelf and seafloor could inadvertently damage or destroy submerged cultural resources if such resources are located within the Study Area and are not avoided. Under Alternative 1, the impact of seafloor devices on cultural resources would remain inconsequential as presented in the 2015 MITT Final EIS/OEIS because (1) seafloor devices are either stationary or move very slowly along the bottom; and (2) the military avoids locations of known obstructions, which include submerged cultural resources (Section 2.3.3, Standard Operating Procedures; and Section 5.4.1, Mitigation Areas for Seafloor Resources). Thus, activities involving seafloor devices are not expected to affect submerged cultural resources.

3.11.2.2.2 Impacts from Physical Disturbance and Strike Stressors Under Alternative 2 (Preferred Alternative)

Under Alternative 2, the number of proposed training and testing events would increase for vessels, decrease for towed in-water devices, increase for non-explosive practice munitions, decrease for military expended materials, and decrease for seafloor devices (see Tables 3.0-12, 3.0-13, 3.0-14, 3.0-15, and 3.0-18, respectively) compared to the numbers in the 2015 MITT Final EIS/OEIS. Under Alternative 2, increases as compared to Alternative 1 would have no appreciable change on the impact conclusions as summarized above under Alternative 1 and presented in the 2015 MITT Final EIS/OEIS.

3.11.2.2.3 Impacts from Physical Disturbance and Strike Stressors Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Physical disturbance and strike stressors as listed above would not be introduced into the marine environment. Therefore, existing environmental conditions of submerged cultural resources would remain unchanged after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer physical disturbance and strike stressors within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for physical disturbance and strike impacts on submerged cultural resources, but would not measurably improve the condition of submerged cultural resources in the Study Area.

3.11.3 Public Comments

The public raised two issues during the scoping period in regard to cultural resources. The issues are summarized in the list below. Comments received from the public during the Draft SEIS/OEIS commenting period related to cultural resources are addressed in Appendix K (Public Comment Responses).

- **U.S. Navy has not consulted with indigenous people for conducting military training –** The 2015 MITT Final EIS/OEIS summarized in Section 3.11.4.2 (Regulatory Determinations) that the 2009 MIRC PA is in effect and satisfies the requirement for consultation as long as the stipulations in that PA are followed. The 2009 MIRC PA was negotiated for all military training activities for the MIRC EIS/OEIS based on consultations with the Guam SHPO, CNMI HPO, Advisory Council on Historic Preservation, and the National Park Service (U.S. Department of Defense, 2009).
- **The Navy should conduct a cultural survey of FDM –** The 2015 MITT Final EIS/OEIS Section 3.11.2.2.1 (Farallon de Medinilla) evaluated the findings of a preliminary archaeological field survey of FDM conducted in 1996 (Welch, 1997). While no archaeological remains were identified during the survey reported by Welch (1997), the reconnaissance effort was

incomplete due to an approaching typhoon and the discovery of "dangerous submunitions" on the island, which prohibited the archaeologists from continuing the work. As part of the PA development, the Navy, in cooperation with the CNMI HPO, is exploring the feasibility of conducting archeological surveys on FDM as well as in the nearshore waters surrounding the Island. Due to the high risk of encountering unexploded ordnance while surveying areas on and around a bombing range, these decisions will require approval from the highest levels of Navy leadership, and no decisions have yet been made.

3.12 Socioeconomic Resources and Environmental Justice

The purpose of this section is to supplement the analysis of impacts on socioeconomic resources and environmental justice presented in the 2015 Mariana Islands Training and Testing (MITT) Final Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS) with new information relevant to proposed changes in training and testing activities conducted at sea and on Farallon de Medinilla (FDM). Information presented in the 2015 MITT Final EIS/OEIS that remains valid is noted as such and referenced in the appropriate sections. New information made available since the publication of the 2015 MITT Final EIS/OEIS is included below to better understand potential stressors and impacts on socioeconomic resources and environmental justice resulting from training and testing activities.

The status and projected trends of socioeconomic resources described in this section represent the affected environment prior to the global coronavirus pandemic and subsequent dramatic declines in economies around the world, including in the United States (U.S.), Guam, and the Commonwealth of the Northern Mariana Islands (CNMI). The governments of many countries, including the United States, as well as the governments of Guam and the CNMI, either limited business operations or mandated the closure of certain businesses across multiple economic sectors. The travel and tourism industry, which many people in Guam and the CNMI are dependent on for employment and income, has been particularly hard hit. The analysis in this section shows that training and testing activities would not significantly impact tourism and related recreational activities in Guam and the CNMI. Tourism in both Guam and the CNMI has grown consistently in recent years, adapting to fluctuations in international travel, and in concert with ongoing training and testing activities.

Comments received from the public during scoping related to socioeconomic resources and environmental justice are addressed in Section 3.12.3 (Public Comments). Comments received from the public during the Draft Supplemental EIS (SEIS)/OEIS commenting period related to socioeconomic resources and environmental justice are responded to in Appendix K (Public Comment Responses). Additional or updated information on environmental justice issues, commercial fishing, subsistence fishing, and tourism in the northern Marianas was added to this section.

Section 3.12 (Socioeconomic Resources) in the 2015 MITT Final EIS/OEIS analyzed subsistence fishing as a socioeconomic resource but did not identify it as an environmental justice issue. This section supplements the analysis of subsistence fishing by expanding the discussion to include other traditional fishing practices and identifying these practices as an environmental justice issue as well as a socioeconomic resource. For the purposes of this analysis, traditional fishing practices are defined by the motivation for the fishing trip and include subsistence, cultural customs, communal sharing, and non-commercial financial benefit (e.g., selling the catch to cover the costs of the fishing trip). These traditional practices, which are longstanding and defining characteristics for many in the local communities on Guam and in the CNMI, are analyzed separately from recreational and commercial fishing in this section.

3.12.1 Affected Environment

The socioeconomic resources and environmental justice issues (i.e., traditional fishing practices) analyzed in this SEIS/OEIS are the same as the resources identified and analyzed in the 2015 MITT Final EIS/OEIS. The training and testing activities described in Chapter 2 (Description of Proposed Action and Alternatives) of this SEIS/OEIS are generally consistent with the training and testing activities analyzed in

the 2015 MITT Final EIS/OEIS and are representative of activities that the Department of Defense (DoD) has been conducting in the MITT Study Area for decades.

The concerns over socioeconomic resources and how they may be impacted by the proposed training and testing activities are similar to those as previously described in the 2015 MITT Final EIS/OEIS. The U.S. Navy's operating procedures to prevent or lessen impacts on local socioeconomic resources, as described in the 2015 MITT Final EIS/OEIS, remain applicable and will continue to be implemented.

As described in detail in the 2015 MITT Final EIS/OEIS, the socioeconomic analysis evaluated how elements of the human environment might be affected by ongoing and proposed training and testing activities in the Study Area. The Navy identified four broad socioeconomic elements based on their association with human activities and livelihoods in the Study Area:

- Commercial transportation and shipping
- Commercial and recreational fishing
- Traditional fishing practices
- Tourism

Each of these resources is an aspect of the human environment that involves economics (e.g., employment, income, or revenue) and social conditions (e.g., enjoyment and quality of life) associated with the marine environment in the Study Area. These four elements were chosen as the focus of the analysis in this section because of their importance to the local economy and the way of life on Guam and the CNMI and the potential for these elements to be impacted by the proposed training and testing activities.

Data and information from government technical documents and reports, scientific journals, and the Navy's marine resources database of publications were reviewed to assess any changes in the socioeconomic environment from conditions described in the 2015 MITT Final EIS/OEIS. The Navy concluded that socioeconomic resources in the marine environment have not changed appreciably since the year 2015.

The growth in Guam's gross domestic product (GDP) has fallen steadily from 2 percent in the year 2012 to -0.3 percent (a decline of 2.3 percent) in the year 2018. For comparison, U.S. GDP growth increased by 2.9 percent in 2018 and by 2.4 percent in 2017 (Hovland et al., 2019a). Increased spending by tourists and spending in the retail sector was offset by decreases in the construction sector following completion of a large hospital and luxury hotel (Hovland et al., 2017a, 2019a). Government spending also decreased with the completion of the Guam Port Authority's improvement plan and fewer DoD construction contracts. However, contracts for construction projects and infrastructure improvements are being awarded to prepare for the relocation of approximately 5,000 Marines and 3,500 dependents from Okinawa, Japan to Guam, which is expected to boost the economy over the next several years (Guam Economic Development Authority, 2018; U.S. Department of the Navy, 2015).

The Guam Economic Development Authority estimates that over 12,800 military personnel and their dependents reside on the island. This includes personnel at Naval Base Guam and Andersen Air Force Base, not just those who support the proposed training and testing activities (Guam Economic Development Authority, 2018). In the 2010 U.S. census, the population of Guam was 159,358 (U.S. Census Bureau, 2018a), and the Central Intelligence Agency World Factbook estimated that the population had grown to 167,358 by the year 2017 (U.S. Central Intelligence Agency, 2018a). Based on these estimates, military personnel and their dependents make up approximately 8 percent of the population of Guam. For comparison, the population on Guam grew by 5 percent from the years 2010

through 2017. In addition to the substantial economic contribution that military personnel and their dependents makes to the Guam economy through spending, taxes (e.g., sales tax), and rental or mortgage payments, the DoD continues to fund infrastructure development projects, and the funding is expected to accelerate with the relocation of the Marines. During the last decade, DoD construction contracts have totaled over $2 billion and have recently averaged nearly $240 million annually. The fiscal year (FY) 2017 National Defense Authorization Act appropriated over $253 million for military construction on Guam (Guam Economic Development Authority, 2018).

The GDP for the CNMI decreased by 19.6 percent in 2018 after increasing by 25.5 percent in 2017 (Hovland et al., 2019b). The decline was driven primarily by decreased visitor spending, including a 50 percent decline in casino gambling. Steady GDP growth from the years 2012 through 2015 preceded large increases in GDP growth in the years 2016 and 2017 and represent a multi-year, positive trend in the economy. It remains to be seen if GDP growth will rebound in the coming years. In the year 2016, the number of tourists visiting the CNMI, particularly from South Korea and China, increased by 10 percent, and private investment increased by over 60 percent, reflecting investment in the gambling industry and construction of the large casino in Garapan as well as smaller hotels on Saipan (Hovland et al., 2017b). However, in 2018, the number of visitors to the CNMI decreased by 19.8 percent, in large part due to the effects of Typhoon Yutu, which devastated the islands of Saipan and Tinian in October 2018. Both private sector spending and government spending are expected to increase in 2019 to support rebuilding and reconstruction efforts (Hovland et al., 2019b).

In the 2010 U.S. census, the population of the CNMI was 53,883 (U.S. Census Bureau, 2018b), and the Central Intelligence Agency World Factbook estimated that the population had declined to 52,263 in the year 2017 (U.S. Central Intelligence Agency, 2018b). Of the 38,679 residents of the CNMI over the age of 16, only 19 reported being in the military in the 2010 U.S. census, indicating that the economic contribution of military personnel and their dependents is not a substantial portion of the CNMI economy (U.S. Census Bureau, 2018c). The Navy has, for the past 5–10 years, had seven vessels assigned to Saipan, which provides substantial funding to the CNMI economy through fuel costs, port fees, and maintenance costs. Five of the vessels are “large, medium speed, roll on/roll off” (or LMSR) vessels and the other two are 2nd Lt. John P. Bobo “BOBO” class vessels. The LMSR vessels transport tracked military vehicles (e.g., tanks) and equipment, and the BOBO class vessels are container and-roll on/roll-off vessels used to transport cargo and ammunition. The annual budget for the five LMSR vessels is approximately $41.5 million, and the annual budget for the two BOBO vessels is approximately $9.5 million. Not every dollar enters directly into the CNMI economy; however, the port fees alone are $900 thousand for each of the seven vessels, totaling $6.3 million annually. Having the seven vessels assigned to Saipan adds millions of dollars into the CNMI economy annually.

Finally, coral reefs are an important element of Guam’s economy, supporting tourism, coastal protection, fisheries, and academic research. At the same time, reefs are also deeply embedded in the island’s culture. For example, the migratory return of traditional fish species are times of special significance, bringing friends and families together to share in the harvest (van Beukering et al., 2007). There are five main uses of coral reefs on Guam, which are integral to the strength of the economy and the health and well-being of many residents: fisheries, recreation and tourism, cultural and traditional uses, education and research, and as shoreline and infrastructure protection (Gorstein et al., 2018; van Beukering et al., 2007).

3.12.1.1 Commercial Transportation and Shipping

The military conducts training and testing activities in operating areas well away from commercially used waterways and inside special use airspace. Refer to Figure 3.12-1 and Figure 3.12-3 of the 2015 MITT Final EIS/OEIS for a depiction of commercial waterways and air routes in proximity to military operating areas and special use airspace in the Study Area. Scheduled training and testing activities are published in Notices to Mariners (NOTMARs) issued by the U.S. Coast Guard and Notices to Airmen (NOTAMs) issued by the Federal Aviation Administration (FAA). These notices are accessible to the public and intended to limit or prevent conflicts between military and non-military uses of shared sea space and airspace.

Following a review of recent literature, including government technical documents and reports, scientific journals, and the Navy's marine resources database of publications, the information presented on commercial transportation and shipping, as described in the 2015 MITT Final EIS/OEIS, has not appreciably changed and remains valid.

3.12.1.1.1 Ocean Traffic

Ocean traffic is the transit of commercial, private, or military vessels at sea, including submarines. In most cases, the factors that govern shipping or boating traffic include the following: adequate depth of water, weather conditions (primarily affecting recreational vessels), availability of fish (affecting the location of commercial and recreational fishing vessels), and water temperature. Higher water temperatures are correlated with an increase in recreational boat traffic, jet skis, and scuba diving activities. Most shipping lanes are located close to the coast, but those that are trans-oceanic start and end to the northwest of Guam.

Areas of surface water within the Study Area are designated as danger zones and restricted areas as described in Code of Federal Regulations (CFR) Title 33 (Navigation and Navigable Waters), Part 334 (Danger Zone and Restricted Area Regulations) and established by the U.S. Army Corps of Engineers. A detailed discussion of danger zones and restricted areas located in the Study Area is provided in Chapter 2 (Description of Proposed Action and Alternatives), Figure 2.7-1 and Table 2.7-1, in the 2015 MITT Final EIS/OEIS. No changes in danger zones and restricted areas in the Study Area have been codified in the Federal Register since the publication of the 2015 MITT Final EIS/OEIS. The danger zone extending from 3 to 12 NM around FDM and the danger zone at Finegayan Small Arms Range are pending approval by the U.S. Army Corps of Engineers; a notification will be published in the Federal Register once they are approved. Both danger zones have been analyzed previously in separate documents, including in the 2012 Mariana Islands Range Complex Airspace Final Environmental Assessment/Overseas Environmental Assessment (U.S. Department of the Navy, 2012), the 2015 MITT Final EIS/OEIS, and the 2010 Mariana Islands Range Complex Final EIS/OEIS (U.S. Department of the Navy, 2010). Refer to Chapter 2 (Description of Proposed Action and Alternatives) in the 2015 MITT Final EIS/OEIS for more information on danger zones in the Study Area.

3.12.1.1.1.1 Guam

Guam has one commercial port, which is located in Apra Harbor. The Port of Guam is the largest U.S. deepwater port in the Western Pacific, handling over 2 million tons of cargo and over 102,000 shipping containers in FY 2016 (Port Authority of Guam, 2017). The average tonnage handled by the port in FY 2015 and FY 2016 was approximately 16 percent greater than the average of the four previous years, and the average number of shipping containers processed by the port in FY 2015 and FY 2016 was 2.6 percent greater than the average of the four previous years (Port Authority of Guam, 2017). Based

on these data, trends in commercial transportation and shipping in Guam appear to be steady and somewhat positive, and the analysis presented in the 2015 MITT Final EIS/OEIS remains valid.

3.12.1.1.1.2 Commonwealth of the Northern Mariana Islands

There are three ports within the CNMI: the Port of Rota, the Port of Tinian, and the Port of Saipan. The Port of Rota, or Rota West Harbor, is located on the southwestern tip of the island of Rota. The port includes a jetty with a pierside water depth of 6–10 feet (ft.), which limits the size of vessels that can access the pier. The Port of Rota is mainly used by ferry boats transporting tourists and residents from Tinian. The Port of Tinian is a small port with three finger piers and a small boat ramp. Pierside water depth ranges from 26 to 30 ft., allowing relatively large vessels to dock. The Port of Saipan is the largest and most advanced of the three CNMI ports, but is nevertheless described as a small seaport by the World Port Source (World Port Source, 2012). The vast majority of cargo transported to the CNMI comes through the Port of Saipan (Commonwealth Ports Authority, 2017). The Port of Saipan has a cargo terminal and an oil terminal with pierside depths up to 25 ft. (World Port Source, 2012). Port facilities are capable of handling loads over 100 tons, and in FY 2016 the port transferred over 560,441 tons of cargo (Commonwealth Ports Authority, 2017). This represents a 36 percent increase over the FY 2015 total and the second straight year of increases (FY 2015 tonnage was 8 percent greater than FY 2014). For all three seaports combined, total tonnage processed in FY 2016 was 581,028 tons, which is a 34 percent increase over the FY 2015 total (Commonwealth Ports Authority, 2017). Based on these data, trends in commercial transportation and shipping in the CNMI have been positive from the years 2014 through 2017, and the analysis presented in the 2015 MITT Final EIS/OEIS remains valid.

3.12.1.1.1.3 Transit Corridor

Major commercial shipping vessels use the shipping lanes for transporting goods between Hawaii, the continental United States, and Asia. However, there are no direct routes between Guam and the United States; stops are made in Asia (usually Japan or South Korea) before continuing on to Hawaii or the continental United States (see Figure 3.12-1 in the 2015 MITT Final EIS/OEIS). Vessels using shipping lanes are outside of military training areas and are required to follow U.S. Coast Guard maritime regulations. Based on available information, overseas commercial shipping traffic potentially passing through the transit corridor, as described in the 2015 MITT Final EIS/OEIS, has not appreciably changed and remains valid.

3.12.1.1.2 Air Traffic

Air traffic refers to movements of aircraft through airspace. Safety and security factors dictate that use of airspace and control of air traffic be closely regulated. Accordingly, regulations applicable to all aircraft are promulgated by the FAA to define permissible uses of designated airspace and to control that use. These regulations are intended to accommodate the various categories of aviation, whether military, commercial, or general aviation.

Special use airspace is a type of airspace used primarily for military operations. Special use airspace has defined dimensions where flight and other activities are confined because of their nature and the need to restrict or prohibit non-participating aircraft for safety reasons. The majority of special use airspace may be used for commercial or general aviation when not reserved for military activities.

One type of special use airspace of particular relevance to the Study Area is a warning area, which is defined in 14 CFR Part 1 as follows:

> "A warning area is airspace of defined dimensions, extending from 3 nautical miles (NM) outward from the coast of the United States that contains activity that may be hazardous to non-participating aircraft. The purpose of such warning areas is to warn non-participating pilots of the potential danger. A warning area may be located over domestic or international waters or both."

On March 13, 2017, the FAA issued a final rule on the modification of the restricted area surrounding FDM (*82 Federal Register 13389*). The modification expands restricted airspace R-7201, which extends 3 NM offshore, by designating a new area surrounding R-7201. The new restricted area airspace, R-7201A, includes the airspace from 3 NM to 12 NM around FDM. Restricted airspace R-7201A became effective on June 22, 2017, and was codified in 14 CFR Part 73. While restricted area airspace R-7201A had not been designated by the FAA prior to completion of the 2015 MITT Final EIS/OEIS, the Navy had requested the airspace and analyzed potential impacts on socioeconomic resources in the 2015 MITT Final EIS/OEIS in anticipation that R-7201A would be approved and designated. For details and figures describing special use airspace in the Study Area, refer to Chapter 2 (Description of Proposed Action and Alternatives).

No changes to existing special use airspace are proposed in this SEIS/OEIS.

3.12.1.1.2.1 Guam

Guam International Air Terminal is the only civilian air transportation facility on Guam. The airport is FAA certified and operated by Guam International Airport Authority, a public corporation and autonomous agency of the Government of Guam. Guam International Air Terminal contains two runways and facilities that were part of the now-closed Naval Air Station Agana. Eight major airlines operate out of Guam International Air Terminal, making it a hub of air transportation for Micronesia. Military aircraft originating from Guam most often transit to one of the three warning areas located south of Guam (Figure 2.1-2).

From FY 2014 through FY 2016, the number of passengers arriving at Guam International Airport increased from approximately 1.34 million to 1.51 million; nearly half originated from Japan (Guam Visitors Bureau, 2017). This represents an increase of over 12 percent, a trend that is expected to continue.

Based on the available information, air traffic on Guam, as described in the 2015 MITT Final EIS/OEIS, has not appreciably changed and remains valid.

3.12.1.1.2.2 Commonwealth of the Northern Mariana Islands

Saipan International Airport is the largest commercial airport in the CNMI and the main gateway for commercial air traffic into the CNMI (Commonwealth Ports Authority, 2005). The airport has an 8,700 ft. runway with adjacent taxiways and can accommodate wide-body aircraft. Direct flights are available from major cities in Japan, South Korea, China, and Guam. A commuter terminal services the islands of Tinian and Rota. Star Mariana Air offers 3 outbound and return flights between Rota and Saipan per day, and 12 outbound and return flights between Saipan and Tinian per day (Star Mariana Air, 2018). Since the completion of the 2015 MITT Final EIS/OEIS, Star Mariana Air opened air service between Rota and Guam, a service made possible by the opening of the light aircraft commuter facility at Guam International Airport (Daleno, 2015).

All commercial flights to Tinian fly into West Tinian Airport. The airport has one runway that is 8,600 ft. by 150 ft. The airport is equipped with a navigational light system for nighttime operations but has no

control tower or additional navigational aids. Rota International Airport has a 6,000 ft. runway capable of handling Boeing 757 or 727 aircraft, but with load restrictions. Tinian and Rota airports primarily support inter-island flights between Tinian, Saipan, Rota, and Guam. All three CNMI airports are FAA certified.

From FY 2014 through FY 2016, the number of passengers departing from CNMI airports increased from 542,744 to 605,952, an increase of over 11 percent (Commonwealth Ports Authority, 2017). The vast majority (over 93 percent) departed from Saipan International Airport. Arrivals increased from 493,851 to 542,126 passengers (nearly 10 percent) over that same timeframe. Airport traffic is forecast to continue to increase with the addition of new airlines providing air service to and from Saipan International Airport (Commonwealth Ports Authority, 2017).

Training and testing activities are conducted at commercial airports, with appropriate planning and coordination with the local port authorities and the FAA. For example, on Tinian, the military conducts aviation training in the military lease area by delivering personnel and cargo to maneuver areas, and providing various support functions to forces already on the ground.

Airspace and sea space may be restricted around FDM. When necessary, the Navy requests that the U.S. Coast Guard issue NOTMARs and that the FAA issues NOTAMs advising the public of potentially hazardous activities occurring in the airspace and sea space surrounding FDM, which may include sea space out to 12 NM from FDM, depending on the nature of the training and testing activities being conducted.

Based on the available information, air traffic and associated activities occurring over islands and sea space in the CNMI, as described in the 2015 MITT Final EIS/OEIS, has not appreciably changed and remains valid.

3.12.1.1.2.3 Transit Corridor

Commercial air routes controlled by the FAA may overlay a portion of the MITT transit corridor. Commercial aircraft typically fly above 30,000 ft. in this area, and would have no interaction with aircraft conducting training and testing activities, which occur within special use airspace (e.g., warning areas) that have minimal overlap with the transit corridor. Air traffic routes for commercial and general aviation flights departing and arriving at Guam International Air Terminal and Saipan International Airport are established such that overlap with military aircraft activities would be avoided.

3.12.1.2 Commercial and Recreational Fishing

Both the CNMI and Guam are categorized as “fishing communities” by the Western Pacific Regional Fishery Management Council. This designation is based on the portion of the population that is dependent upon fishing for subsistence; the economic importance of fishery resources to the islands; and the geographic, demographic, and cultural attributes of the communities (Western Pacific Regional Fishery Management Council, 2009, 2019).

Fishing is an integral part of the culture and way of life in the CNMI and Guam (Hovland et al., 2019a, 2019b). Most fishers do not fish exclusively for commercial, recreational, or subsistence benefit but rather for some combination of the three (Hospital & Beavers, 2012; Hospital & Beavers, 2014; Tibbats & Flores, 2012; Western Pacific Regional Fishery Management Council, 2019). In a survey conducted in 2016 as part of the National Oceanic and Atmospheric Administration’s Coral Reef Conservation Program, over 30 percent of Guam residents reported participating in fishing or gathering of marine

resources (Hovland et al., 2019a). Even more residents of the CNMI (38 percent) reported engaging in those activities (Hovland et al., 2019b).

Commercial fishing takes place throughout the Study Area from nearshore waters adjacent to Guam and the CNMI, offshore banks, and pelagic waters. Sportfishing peaks in summer (June through August) when popular sport fish, including blue marlin and yellowfin tuna, are most abundant. Skipjack tuna are present year-round, but are most abundant in summer.

3.12.1.2.1 Guam

Commercial and recreational fishing on Guam is typically divided into three types: bottom fishing, coral reef fishing, and pelagic fishing. A 2011 survey of 147 small boat fishers on Guam revealed the traditional and cultural importance of fishing to the people of Guam. Fishers responding to the survey reported having fished from boats for an average of 20 years (Hospital & Beavers, 2012). Although 70 percent of fishers reported selling a portion (on average 24 percent) of their catch, the motivation was not to supplement their income, but mainly to defray some of the costs associated with fishing trips (e.g., fuel costs). In 2018, the average cost of a fishing trip in bottom fish fishery was $57, with 47 percent ($27) spent on fuel. Since 2009, the average cost per fishing trip has ranged from $36 to $72. The cost of fuel has been the primary expense, ranging between 38 and 50 percent of the overall cost. Expenses for ice, fishing gear, and bait make up an approximately equal portion of the remaining cost for a fishing trip. Considering that the price of fuel is heavily influenced by the global oil market, the primary cost associated with fishing is largely beyond the control of fishers (Western Pacific Regional Fishery Management Council, 2019). Even though fishing is no longer the primary source of income for many fishers, it is an important part of the social and cultural history of the people of Guam, and it remains a vital part of local communities (van Beukering et al., 2007). This point is illustrated by the manner in which fishers distribute their catch. Respondents to the survey (Hospital & Beavers, 2012) reported consuming 29 percent of their catch at home, giving away 42 percent of their catch, and selling 24 percent of their catch. The remaining balance was either released or used to barter for other goods. The survey also noted the importance of fish-aggregating devices to small boat fishers. Ninety-six percent of fishers reported having fished at a fish-aggregating device during the previous 12 months and on more than half of all fishing trips (Hospital & Beavers, 2012). The National Coral Reef Monitoring Program report estimated subsistence fishing accounted for 30 percent of coral reef and bottom fish species landed in 2016 (Gorstein et al., 2018).

More information on fishing practices on Guam, including gear types, target species, charter fishing, commonly used harbors and marinas, and popular fishing sites, is presented in Section 3.12 (Socioeconomic Resources) of the 2015 MITT Final EIS/OEIS.

Commercial fisheries landings for all species from the years 2005 through 2009 were presented in Section 3.12 (Socioeconomic Resources) of the 2015 MITT Final EIS/OEIS (see Table 3.12-2). Total fisheries landings (in pounds of fish) and value (in U.S. dollars) steadily decreased from 2010 through 2015 before leveling off in 2016 (Figure 3.12-1, only the 2013–2018 data are shown). Total commercial landings (pounds and value) increased dramatically in 2017 and then decreased the following year to amounts comparable to 2013 and 2014 totals (Pacific Islands Fisheries Science Center, 2016a, 2019). The average estimated price per pound for commercial landings has also fluctuated, from a recent low of $2.94 per pound in the year 2015 to a high of $3.08 per pound in the year 2014 (Pacific Islands Fisheries Science Center, 2019).

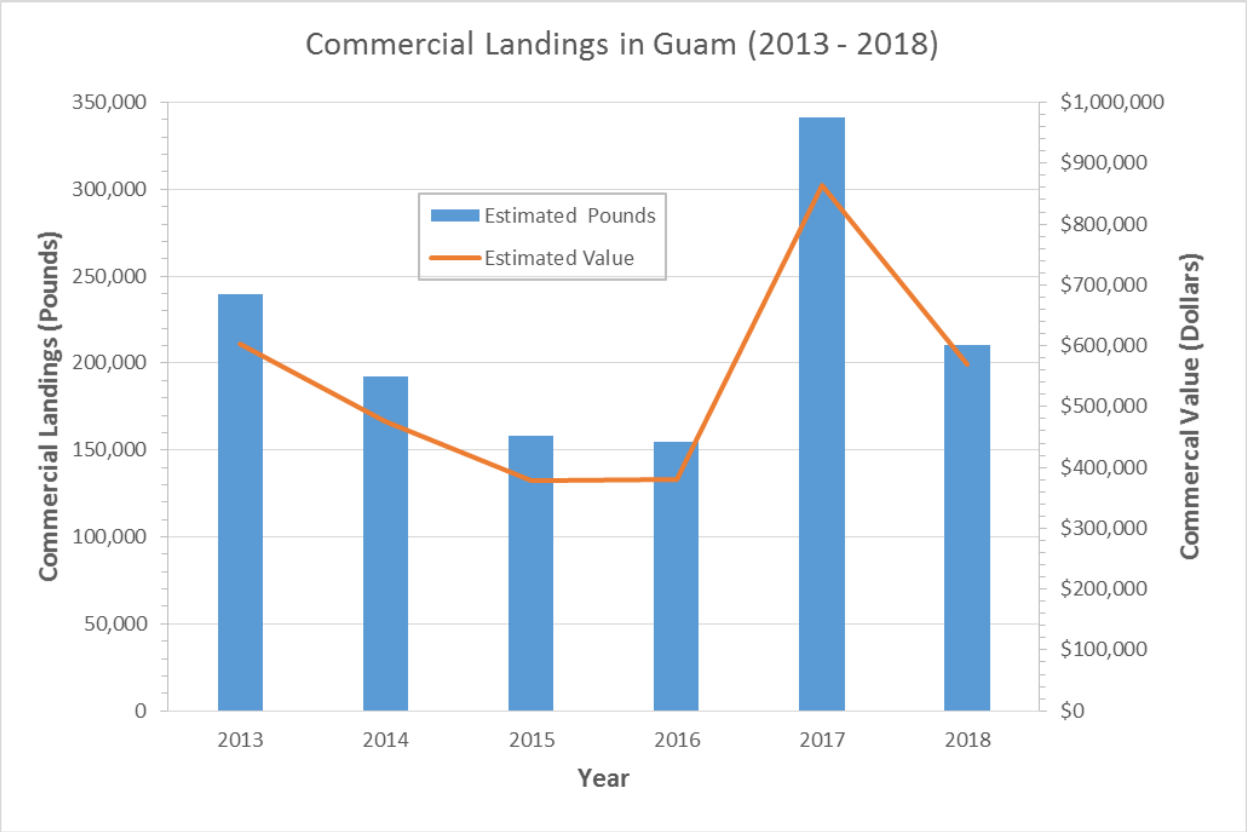

Figure 3.12-1: Commercial Fisheries Landings in Guam from the Years 2013 through 2018

The declining trend in fisheries landings is consistent with the results presented by Weijerman et al. (2016), which documented a decline of over 60 percent in the annual catch of reef fish around Guam between the years 1985 and 2012. The declining catch was consistent with a decline in reef fish biomass around the island. Similar declines in reef fish fisheries have been reported for other regions in Micronesia (Cuetos-Bueno & Houk, 2018). Rather than a single cause, it appears that interconnected economic, social, and environmental factors are combining to exert pressure on remote island fisheries. For example, on the economic front, a growing demand for fresh fish worldwide has driven the development of technology to enable the transportation of fresh fish from more remote areas, including islands in Micronesia, which were not previously commercially viable. Expanding the commercial market to include these remote island fisheries has increased commercial fishing in these remote locations to the point of becoming unsustainable (Cuetos-Bueno & Houk, 2018).

3.12.1.2.2 Commonwealth of the Northern Mariana Islands

Similar to Guam and other Pacific island communities, fishing in the CNMI is performed for commercial and recreational purposes as well as for subsistence and related cultural practices (Western Pacific Regional Fishery Management Council, 2019). Hospital and Beavers (2014) surveyed 112 small boat fishers from Saipan, Tinian, and Rota. Based on the reported information, the researchers were able to characterize fishing practices in the CNMI by analyzing the level of fishing activity, participation in commercial markets, trip costs and other fishing-related expenditures, the social and cultural importance of fishing, fishing as a means of subsistence, and attitudes and perceptions of fishing conditions and fisheries management. The results of the survey are similar to the responses provided by

small boat fishers from Guam and do not appreciably change the conclusions presented in Section 3.12 (Socioeconomic Resources) of the 2015 MITT Final EIS/OEIS.

The results of the survey highlighted the following characteristics of the small boat fishing community. Demographically, small boat fishers are more likely to identify as Chamorro relative to the general population. Approximately 70 percent of boat owners reported that they allowed others to use their boat, indicating that many boats are shared by multiple fishers. As with fishers in Guam, small boat fishers in the CNMI reported that fish-aggregating devices were important, and 70 percent reported using a fish-aggregating device at least once over a 12-month period. Fishers in the CNMI reported consuming approximately 28 percent of their catch at home, giving away 38 percent of their catch, and selling approximately 29 percent. The remaining 5 percent of the catch was either released or exchanged for goods and services (Hospital & Beavers, 2014). However, less than half of fishers in the CNMI were able to sell all of the catch that they wanted to sell, indicating that the market is limited.

Hospital and Beavers (2014) concluded that the CNMI small boat fisheries are a complex mix of subsistence, cultural, recreational, and quasi-commercial fishing practices and validated the socioeconomic importance of fishing to the people of the CNMI.

Small boat fishers were also asked in the survey conducted by Hospital and Beavers (2014) if military activities had affected their fishing trips in the 12 months prior to completing the survey. Approximately one-third of fishers reported trips had been affected by military exercises; however, the survey did not gather information on how trips were affected. While not explicitly clear, the results of the survey imply that waters around FDM were of particular interest to fishers and that activities at FDM were the primary source of impacts on fishing trips. Starmer (2005) noted that many target fish species have become less common in waters around Saipan and Tinian and are more abundant in waters surrounding FDM, which may be an incentive for fishers to attempt to fish near FDM rather than at other unrestricted locations. The Navy has conducted periodic surveys of the waters around FDM and observed that the abundance and size of reef fishes around the island is equal to or greater than at many of the inhabited islands in the Mariana Archipelago where fishing regularly occurs (Smith & Marx, 2016).

A 2016 survey of CNMI fishers reinforced similar themes reported on in previous surveys (Ayers, 2018; Hospital & Beavers, 2014). Survey responses were separated into four broad categories: economic issues; role of government, institutions, and military impacts; fisheries and resource trends; and social and educational issues. Out of 166 individual responses, 70 were related to economic issues, with nearly half of those (33) expressing concerns over a diminishing market for locally caught fish. Impacts from tourism were mixed, with some respondents uneasy about increased pollution while others were hoping more tourists would lead to a greater demand for fish (Ayers, 2018). Thirteen comments were associated with impacts from military activities, with 11 of the comments coming from Tinian fishers. (2 from Saipan and 0 from Rota). Tinian fishers reported being affected by closures of certain favorable shoreline casting areas and preferred trolling areas when military training activities took place (Ayers, 2018). Most of the remaining comments were associated with other topics of interest to fishers (e.g., regulations, illegal fishing, nutrition) but were less relevant to analysis in the SEIS/OEIS.

Commercial fisheries landings in the CNMI for all species from the years 2005 through 2009 were presented in Section 3.12 (Socioeconomic Resources) of the 2015 MITT Final EIS/OEIS (see Table 3.12-2 in that document). From the years 2010 to 2011, total fisheries landings (in pounds of fish) decreased, but then began a positive trend, reaching a high of nearly 350,000 pounds in the year 2013. In the years

following, landings generally declined to about 200,000 pounds in the year 2018 (Figure 3.12-2) (Pacific Islands Fisheries Science Center, 2016b). The value of commercial landings followed a similar pattern, reaching a high of over $865,000 in the year 2014 but decreasing by 34 percent in the year 2015. Following the trend in pounds, the value of commercial landings in the CNMI decreased steadily between 2016 and 2018 (Pacific Islands Fisheries Science Center, 2019). The average estimated price per pound varied from one year to the next, ranging between $2.97 in the year 2013 and $3.74 in the year 2015.

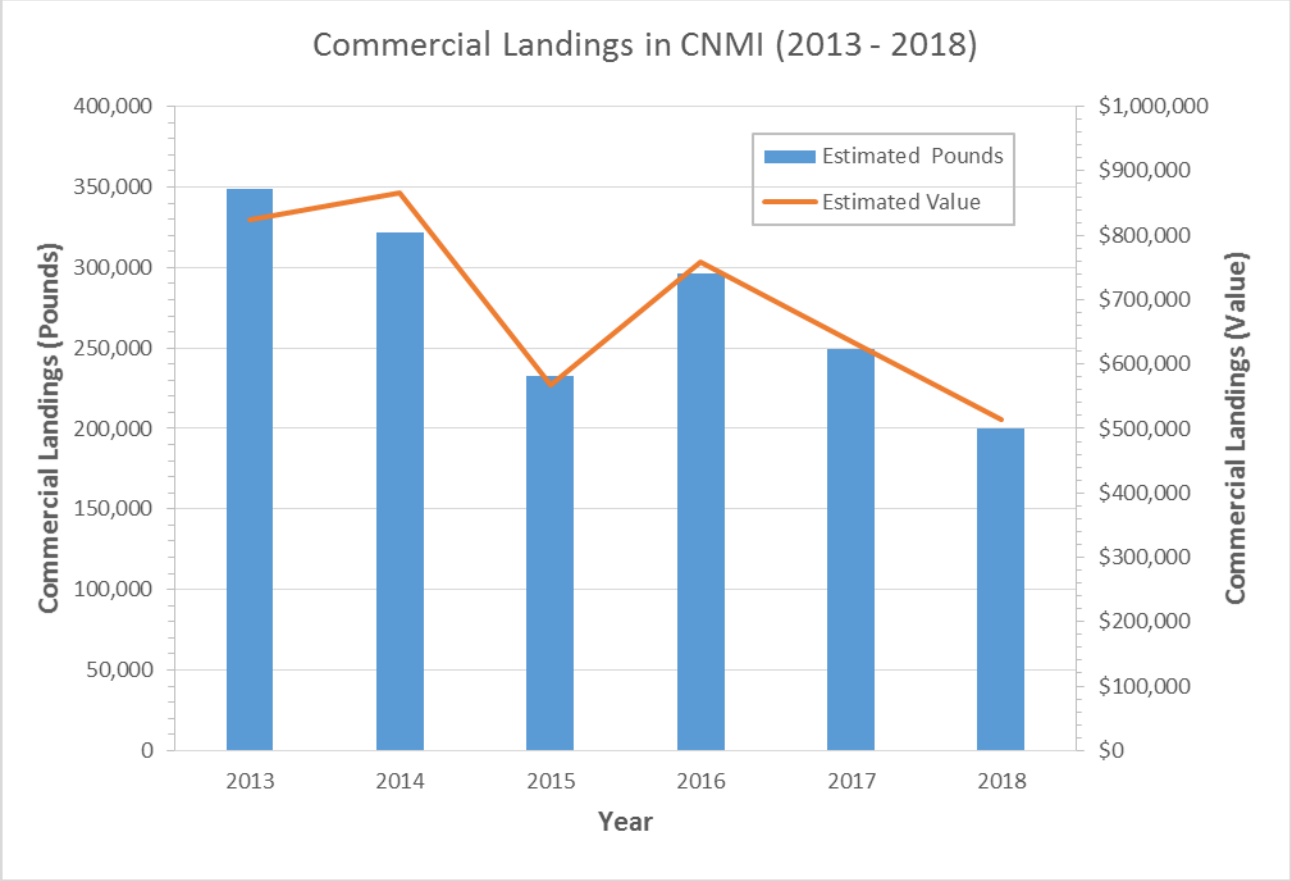

Figure 3.12-2: Commercial Fisheries Landings in the CNMI from the Years 2013 through 2018

The trend in commercial fisheries landings, pounds and value, from the years 2013 through 2018 has generally declined, particularly over the most recent three years (2016–2018). The historical trend of landings in the coral reef fishery, one of the three major fisheries in the CNMI and Guam and of particular importance to traditional fishers, clearly shows a decline (Cuetos-Bueno & Houk, 2014). Since the 1950s, the researchers estimate that commercial and non-commercial reef fishery landings in the CNMI have declined by 39–73 percent. In addition to greater fishing pressure from commercial, recreational, and traditional fishing, particularly near population centers, a decline in the health and extent of coral reefs in the region has contributed to decreased landings. See Section 3.8 (Marine Invertebrates) for more information on coral reefs in the Study Area. Commercial fishing in the CNMI is not economically viable for most fishers given that the local price per pound for most species has remained relatively fixed for the past 25 years (Ayers, 2018). The rising costs of fishing gear, tackle, boats and associated maintenance, and fuel have made it increasingly difficult for CNMI fishers to make a living as commercial fishers (Ayers, 2018; Hospital & Beavers, 2014). In 2017, the average cost of a

fishing trip in the bottomfish fishery was $38, with 84 percent ($32) spent on fuel. Since 2009, the average cost per fishing trip has ranged from $19 to $65; consistent with the Guam bottomfish fishery, the cost of fuel has been the primary expense, ranging between 78 and 92 percent of the overall cost. Since the price of fuel is heavily dependent on the global oil market, the primary cost associated with fishing is largely beyond the control of fishers (Western Pacific Regional Fishery Management Council, 2019).

The majority of training and testing activities occur offshore in deep waters and not in close proximity to coral reefs, which are located in relatively shallow, nearshore waters. Refer to Chapter 2 (Description of Proposed Action and Alternatives) and Appendix A (Training and Testing Activities Descriptions) for information on where the proposed training and testing activities typically occur. Refer to Section 3.8 (Marine Invertebrates) for information and the locations of coral reefs in the Study Area. Some activities, such as those occurring at FDM, have the potential to affect coral reefs and, by extension, the coral reef fishery. Surveys conducted by Smith and Marx (2016) indicate that the health, abundance, and biomass of reef fish populations in the vicinity of FDM are comparable or superior to populations at other locations in the CNMI, likely due to the de facto protection from fishing that results from restricting access to the area around FDM. The authors conclude that training and testing activities are having little to no negative impact on the reef fish fishery. Having a de facto protected area around FDM may benefit the reef fish fishery in the CNMI, beyond the restricted area around FDM; however, restricting access to nearshore areas (within 3 NM) around FDM where target species occur limits the ability for fishers to gain access to potentially productive fishing sites.

3.12.1.2.3 Transit Corridor

There are no data on commercial or recreational fishing within the transit corridor. Navy vessels using the corridor travel east from Guam directly into ocean waters far from shore. Due to the distance from land and a lack of known fishing areas within the corridor, it is assumed that there is limited to no commercial and recreational fishing activity within the transit corridor.

3.12.1.3 Tourism

Coastal tourism and associated recreational activities that tourists participate in can be defined as the full range of tourism, leisure, and recreationally oriented activities that take place in the coastal zone and offshore coastal waters. From an economic point of view, tourism drives infrastructure development (e.g., hotels, resorts, restaurants, vacation homes), businesses (e.g., retail shops, marinas, fishing tackle stores, dive shops), and services (e.g., guided tours, charter boat cruises, cultural exhibitions arranged for tourists) that create local jobs and tax revenue for the local government. In-water activities that attract tourists to Guam and the CNMI include swimming, snorkeling, scuba diving, wildlife watching (e.g., dolphin cruises), pleasure boating, sailing, and annual events such as the Rota Blue triathlon.

3.12.1.3.1 Guam

Tourism is Guam's largest industry; it generates $1.5 billion annually, makes up 60 percent of business revenue, and supports 33 percent of all employment on the island (Guam Visitors Bureau, 2014, 2017). In 2016, Guam welcomed over million 1.53 million visitors, which is the highest annual total for visitor arrivals on Guam in any calendar year (Guam Visitors Bureau, 2017). Visitors from Japan accounted for half, approximately 752,000 visitors; however, Japanese visitors made up 76 percent of the market in 2010 (Guam Visitors Bureau, 2014, 2017). The decline in the Japanese market share is not entirely due to a reduction in visitors from Japan. It is also attributed to Guam's efforts to broaden its tourism market

to include visitors from other countries, particularly China, which has the fastest-growing visitor market in the world. China contributed just 0.7 percent of visitors to Guam in the year 2012, but 1.8 percent in the year 2016, and the Guam Visitor's Bureau projects that Chinese visitors will make up between 5.7 and 17.5 percent of tourists by the year 2020 (Guam Visitors Bureau, 2014, 2017). The other significant visitor markets in the year 2016 were South Korea (34.8 percent), the United States (5.2 percent), and Taiwan (2.8 percent).

Approximately 23 percent of the value of Guam's GDP in the year 2016 was from spending by the federal government, including defense spending (Hovland et al., 2017a). Revenue from the government has provided Guam with an economic buffer against fluctuations in the tourism industry. Tourism in Guam has continued to increase both in the number of visitors and in its contribution to the economy since completion of the 2015 MITT Final EIS/OEIS. Even though trends in tourism are positive, the existing conditions and the results of the analysis of impacts on tourism presented in the 2015 MITT Final EIS/OEIS remain valid.

3.12.1.3.2 Commonwealth of the Northern Mariana Islands

Tourism is the largest industry in the CNMI and has driven a positive growth in GDP over the past five years (Hovland et al., 2017b; Marianas Visitors Authority, 2016). Visitors from South Korea and China each made up 38 percent of the market in FY 2015, increasing their market share by 39 percent and 15 percent over FY 2014, respectively. The number of visitors from Japan, which has historically been the dominant market, made up just 18 percent of visitors in FY 2015, a 23 percent decrease over FY 2014. The decline is primarily attributed to a poor exchange rate for Japanese travelers and Japan's stagnant economy; however, it has also been a challenge to maintain regular direct flights from Japan to the CNMI (Marianas Visitors Authority, 2016). Visitors from Russia declined by 80 percent in FY 2015 due to the suspension of direct flights to the CNMI, economic sanctions instituted by the European Union and the United States, and a drop in global oil prices. In FY 2016, the total number of visitors from all countries combined increased by 10 percent over FY 2015, exceeding 500,000 for the first time in the past 10 years (Hovland et al., 2017b; Marianas Visitors Authority, 2018). Visitation continued to increase in FY 2017, reaching 653,150 arrivals, due primarily to increases in the number of visitors from South Korea and China and despite declining visitation from Japan (Marianas Visitors Authority, 2018). In FY 2018, the number of visitors declined for the first time since FY 2011, falling to 607,593; although, with the exception of FY 2017, that was the highest total over the past 10 years. However, the trend continued into FY 2019, and as of July 2019, overall visitation was down sharply by more than 32 percent compared to FY 2018, and all major markets (South Korea, China, and Japan) were down between 20 and 73 percent (Marianas Visitors Authority, 2019).

Cruise ships have recently begun visiting the Northern Mariana Islands, fueling a budding tourism industry on Pagan Island and the Maug Islands (Silversea, 2019). Cruises offered by Silversea depart from Guam and visit Saipan before moving north, with a final destination in Japan.

Approximately 2 percent of the value of the CNMI's GDP in the year 2016 was from spending by the federal government and 21 percent was from spending by the territorial government (Hovland et al., 2017b). Government spending buffers the CNMI economy against downturns in tourism; however, the CNMI does not receive the same proportion of federal funds as Guam, leaving the CNMI economy more susceptible to fluctuations in tourism. Even though trends in tourism are positive, the existing conditions, as presented in the 2015 MITT Final EIS/OEIS, and the results of the analysis of impacts on tourism remain valid.

3.12.1.3.3 Transit Corridor

It is assumed that there is little to no tourism activity within the transit corridor due to the distance from land and because the majority of tourism activities occur in nearshore waters.

3.12.1.4 Environmental Justice

The U.S. Environmental Protection Agency defines environmental justice as the "fair treatment" and "meaningful involvement" of all people regardless of race, color, national origin, or income with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies (U.S. Environmental Protection Agency, 2016). The phrase "fair treatment" means that no group of people should bear a disproportionate share of the negative environmental consequences resulting from industrial, governmental, and commercial operations or policies. The phrase "meaningful involvement" means that

- "people have an opportunity to participate in decisions about activities that may affect their environment or health,
- the public's contribution can influence the regulatory agency's decision,
- their concerns will be considered in the decision-making process, and
- the decision makers seek out and facilitate the involvement of those potentially affected" (Federal Aviation Administration, 2015).

Based on data from the 2010 U.S. Census, the population over the age of 16 in Guam was 113,067, which represents the working population (U.S. Census Bureau, 2018a). Of those people who are of working age, 61.4 percent were employed in the civilian workforce and 4.4 percent were in the armed forces. According to the census data, 2.3 percent of employed people in Guam also participated in a subsistence activity (e.g., fishing), and just 0.6 percent of people who were not in the labor force participated in a subsistence activity. Therefore, less than 3 percent of the working age population reported participating in a subsistence activity in the year 2010, which is likely to be fishing, but does not exclude other activities, such as growing crops. In the CNMI, 38,679 people are of employable age (at least 16 years old), and 64.2 percent are employed in the civilian workforce (U.S. Census Bureau, 2018b). According to the census data, 2.9 percent of employed people in the CNMI also participated in a subsistence activity (e.g., fishing), and just 0.6 percent of people who were not in the labor force participated in a subsistence activity. Therefore, approximately 3 percent of the working age population in the CNMI reported participating in a subsistence activity in the year 2010.

Traditional fishing practices were identified by residents of Guam and the CNMI as having the potential to be impacted by the proposed training and testing activities occurring at sea and on FDM.

3.12.1.4.1 Traditional Fishing Practices

Lower-income communities are more likely to engage in subsistence fishing and may be disproportionately affected by declines in a fishery (Allen & Bartram, 2008; Allen, 2013; Hospital & Beavers, 2014; Office of Environmental Health Hazard Assessment, 1997). An important part of the cultural heritage of local communities practicing traditional fishing is sharing the catch, which lower-income individuals and families in the community may depend on as a source of nutrition whether or not they fish. Most subsistence fishing is expected to occur within 3 NM from shore, because the smaller boats that are typically used by traditional fishers are not equipped for long trips offshore, and traditional fishing sites are generally associated with nearshore reefs.

The U.S. Environmental Protection Agency considers subsistence fishers to be people who rely on non-commercial fish as a major source of protein (U.S. Environmental Protection Agency, 2002). Many communities worldwide meet this definition of subsistence fishing, including local communities on Guam and the CNMI. However, many of these communities engage in traditional fishing practices not just for subsistence or financial reasons but as part of their cultural heritage and social customs (U.S. Environmental Protection Agency, 2002). For example, Native Alaskans regard traditional fishing practices as a way of life, not a marginal existence to overcome or to rise above.

> "It's something rich. It's spiritual. It's economic. It's social. It's getting together with your friends and your relatives going out there harvesting, and sharing with elders, sharing with widows, and that's a pride we get." (U.S. Environmental Protection Agency, 2002).

Although this definition is from a native Alaskan fisher, similar input was received from Asian and Pacific Islander groups, more closely linked to fishers from Guam and the CNMI. For example, ethnic Asian and Pacific Islanders residing in the United States, "consider seafood collection and consumption as healthy activities that reflect a homelike lifestyle" (U.S. Environmental Protection Agency, 2002).

Traditional fishers tend to consume non-commercial fish or shellfish at higher rates than other populations who fish, and for a greater percentage of the year, because of cultural customs or economic factors. In the United States, there are no particular criteria or thresholds (such as income level or frequency of fishing) that definitively describe traditional fishers. Allen (2013) reported on the complicated issue of defining traditional fishers in the western Pacific region, including Guam and the CNMI. Many fishers identifying as traditional or subsistence fishers also participate in recreational and commercial fishing. It is not always clear when fishers are engaging in subsistence fishing, fishing for cultural or social reasons, fishing for financial gain or leisure, or some combination, which can occur even on a single fishing trip. Nevertheless, the contribution of non-commercial traditional fishing to the GDP of U.S. Pacific island territories is likely underestimated in fisheries catch data by as much as five times (Cuetos-Bueno & Houk, 2014; Zeller et al., 2014).

The multifaceted nature of traditional fishing practices and their contribution to local communities remains difficult to quantify; however, it is clear that there is both a social and economic benefit to many in those communities even for those who rarely or never actually fish (e.g., someone who doesn't fish may receive fish at low or no cost). Allen (2013) offers a framework to better define traditional fishing practices that is aimed at disentangling traditional fishing from other types of fishing (e.g., recreational or commercial fishing). Discerning specific details on when and to what degree traditional fishing is occurring in the Study Area is beyond the scope of this analysis. However, it is clear that traditional fishing is more than an economic necessity; it is an important part of the cultural and social identity of indigenous peoples and Asian immigrant communities living in Guam and in the CNMI (U.S. Environmental Protection Agency, 2002).

3.12.1.4.1.1 Guam

The 2015 NMFS stock assessment report for the bottomfish fishery in Guam and the CNMI concluded that the fishery was not overfished through the year 2013, and modeled projections predicted that the fishery was very unlikely to become overfished by the year 2017 (Yau et al., 2016). Consistent with those projections, the NMFS fisheries stock status report for the fourth quarter of 2019 reported that the bottomfish fishery in Guam and the CNMI was not overfished (National Marine Fisheries Service, 2020). However, coral reef fisheries, which support most traditional fishing in the Study Area, have declined over the past 30 years (Weijerman et al., 2016). From 1985 through 1990 the average annual catch was

approximately 100 tons, but from the years 2007 through 2012 the average annual catch decreased to 37 tons. The total estimated fishing effort remained relatively stable over the time period (1985–2012), indicating that fishing for reef fishes as an activity, whether for recreation, subsistence, or commercial purposes, on Guam and the CNMI was not responsible for the decline in the catch. Weijerman et al. (2016) also noted that the decline was distributed over most gear types, indicating that a change associated with a particular gear type (e.g., a restriction on usage) was not disproportionately affecting the catch. Furthermore, historical data on the biomass of targeted fish species showed a general decrease in biomass from the years 1985 through 2012 (Weijerman et al., 2016). These results show that the decline in the reef fish fishery has been occurring for decades and is expected to continue.

If the availability of target species in the reef fish fishery continues to decline, the annual catch from traditional fishers will also decline. As noted above, quantifying the total catch from traditional fishing is a complex issue that makes measuring and predicting the impacts of a decline challenging. Even though the catch may continue to decline, traditional fishing practices may not be proportionately impacted, because the social and cultural aspects of the traditional fishing are not necessarily dependent on successfully catching and harvesting fish. As noted in the research by Weijerman et al. (2016), fishing effort (i.e., a measure of how much fishing occurred) remained relatively stable despite recent declines in the catch. While target fish species may be less available, which may have a greater impact on the success of traditional practices like subsistence fishing, overall traditional fishing practices on Guam have not changed appreciably since the 2015 MITT Final EIS/OEIS, and the analysis in the 2015 MITT Final EIS/OEIS remains valid. Refer to Section 3.12.2.3 (Subsistence Use) of the 2015 MITT Final EIS/OEIS for a discussion of subsistence fishing practices on Guam.

3.12.1.4.1.2 Commonwealth of the Northern Mariana Islands

As reported for Guam (see Section 3.12.1.4.1.1, Guam) NMFS stock assessment report predicted that the bottomfish fishery in the CNMI was highly unlikely to become overfished by the year 2017 (Yau et al., 2016). However, the catch from the non-commercial reef fish fishery in the CNMI, which supports most traditional fishing, has historically been underestimated yet has clearly been in decline since the late 1970s based on data from a new reporting system introduced at that time (Cuetos-Bueno & Houk, 2014). Since the 1950s, the catch, which was estimate to have been 450 tons per year, has declined by 39 to 73 percent depending on the scenario used to extrapolate the survey data. More recently the catch is estimate to have declined from 250 tons per year in the year 2005 to 100 tons in the year 2012, a decrease of 60 percent (Cuetos-Bueno & Houk, 2014).

Similar to traditional fishing practices in Guam, if the availability of target species in the reef fish fishery in the CNMI continues to decline, the annual catch from traditional fishers is likely to decline. Traditional fishers that are more dependent on a successful catch (e.g., subsistence fishers) may be impacted to a greater degree than fishers who engage in traditional practices for social and cultural reasons. As noted in recent research by (Weijerman et al., 2016), fishing effort remained relatively stable despite declines in the catch. While target fish species may be less available, traditional fishing practices in the CNMI have not changed appreciably since the 2015 MITT Final EIS/OEIS, and the analysis in the 2015 MITT Final EIS/OEIS remains valid. Refer to Section 3.12.2.3 (Subsistence Use) of the 2015 MITT Final EIS/OEIS for a discussion of subsistence fishing practices in the CNMI.

3.12.1.4.1.3 Transit Corridor

There are no data on traditional fishing practices occurring in the transit corridor. Navy vessels using the corridor travel east from Guam directly into ocean waters far from shore. It is assumed that traditional fishing practices do not typically occur within the transit corridor, because the corridor is a transoceanic route and the majority of traditional fishing occurs in nearshore waters.

3.12.2 Environmental Consequences

The 2015 MITT Final EIS/OEIS analyzed training and testing activities currently occurring in the Study Area and considered all potential stressors related to socioeconomic resources. Stressors applicable to socioeconomic resources in the Study Area are the same stressors analyzed in the 2015 MITT Final EIS/OEIS:

- Accessibility (to the ocean and the airspace)
- Airborne acoustics (weapons firing, aircraft, and vessel noise)
- Physical disturbance and strike (aircraft, vessels and in-water devices, military expended materials)
- Secondary stressors (from availability of resources)

This section evaluates how and to what degree potential impacts on socioeconomic resources from stressors described in Section 3.0 (Introduction) may have changed since the analysis presented in the 2015 MITT Final EIS/OEIS was completed. Tables 2.5-1 and 2.5-2 in Chapter 2 (Description of Proposed Action and Alternatives) list the proposed training and testing activities and include the number of times each activity would be conducted annually and the locations within the Study Area where the activity would typically occur under each alternative. The tables also present the same information for activities described in the 2015 MITT Final EIS/OEIS so that the proposed levels of training and testing activities under this SEIS/OEIS can be easily compared. The analysis includes consideration of the mitigation that the Navy would implement to avoid or reduce potential impacts on seafloor resources, some of which are important socioeconomic resources.

3.12.2.1 Accessibility (to the Ocean and Airspace)

3.12.2.1.1 Impacts from Limits on Accessibility Under Alternative 1

In some cases, under Alternative 1, the number of proposed training and testing events would change as compared to the number of events proposed in the 2015 MITT Final EIS/OEIS (see Tables 2.5-1 and 2.5-2 in this SEIS/OEIS for changes in the number of annual events for specific activities). Training and testing activities that would increase under Alternative 1 would potentially increase limits on accessibility to areas of the Study Area that are used by both the military and the public. However, decreases in the number of training and testing events occurring in areas of co-use would potentially decrease the number of times access to those areas is restricted. Only some training and testing activities that either increased or decreased have the potential to impact accessibility and require further analysis to supplement the analysis in the 2015 MITT Final EIS/OEIS.

The activities that changed (i.e., increased or decreased) are identified (highlighted) in Tables 2.5-1 and 2.5-2 and in Appendix F (Training and Testing Activities Matrices) in this SEIS/OEIS. The two tables and Appendix F were used together to identify which of the activities that either increased or decreased have the potential to impact accessibility in the Study Area. For example, five Gunnery Exercise (GUNEX) (Surface-to-Air–Large Caliber) activities per year were proposed in the 2015 MITT Final EIS/OEIS, and six are proposed under Alternative 1 in this SEIS/OEIS (Table 2.5-1). Referring to Table F-1 (Stressors by

Training Activity) in Appendix F, the activity GUNEX (Surface-to-Air) is identified with a check mark as having the potential to limit accessibility (listed as a socioeconomic stressor) by the public to areas in the Study Area.

As shown in Appendix F (Training and Testing Activities Matrices), the majority of the proposed training and testing activities introduce stressors on accessibility, which supports using the number of annual events proposed under each alternative as a metric to compare impacts. Generally, activities involving the use of aircraft, vessels, or in-water devices may temporarily limit accessibility to areas of the Study Area. Table 3.0-11 in Section 3.0 (Introduction) shows that the number of annual events using aircraft would decrease by about 10 percent under Alternative 1; however, Table 3.0-12 and Table 3.0-13 show that the number of annual events using vessels and in-water devices would increase by about 15 and 4 percent, respectively, under Alternative 1 compared to totals in the 2015 MITT Final EIS/OEIS.

After reviewing the changes in the numbers and types of proposed training and testing activities with the potential to limit accessibility, the Navy determined that potential impacts on accessibility would not be substantially different from the 2015 MITT Final EIS/OEIS. Therefore, the analysis, supplemented below, from the 2015 MITT Final EIS/OEIS remains valid.

Training and testing activities have the potential to temporarily limit access to areas of the ocean, which has the potential to impact commercial transportation and shipping, commercial recreation and fishing, traditional fishing practices, and tourism in the Study Area. The military requests that the U.S. Coast Guard issue NOTMARs to warn the public of upcoming training and testing activities requiring the exclusive use of sea space and to ensure the safety of the public and military personnel. Data on the number of NOTMARs issued from the years 2013 through 2019 for FDM and W-517 were added to the previous three years of data presented in the 2015 MITT Final EIS/OEIS (Figure 3.12-3). The data show that the number of NOTMARs issued for FDM peaked at 56 in the year 2017, and for W-517 the peak was in the year 2016 at 50 NOTMARs. The average number of NOTMARs issued annually from the years 2010 through 2018 was 41 for FDM and 36 for W-517.

Prior to 2017, no NOTMARs were issued for the recently established warning areas W-11, W-12, and W-13. In the year 2017, two NOTMARs were issued for W-12, affecting a total of five days. In the year 2018, six NOTMARs were issued for W-12 (affecting 13 days), and one NOTMAR affecting one day was issued for W-11. For 2019, there were 6 NOTMARs issued for W-11, 3 for W-12, and 15 for W-13. The corresponding number of days affected by activities in the three warning areas was 27, 22, and 37, respectively. As activity in the three newer warning areas has increased, there has been a corresponding decrease in the level of activity in W-517 (Figure 3.12-3 and Figure 3.12-4).

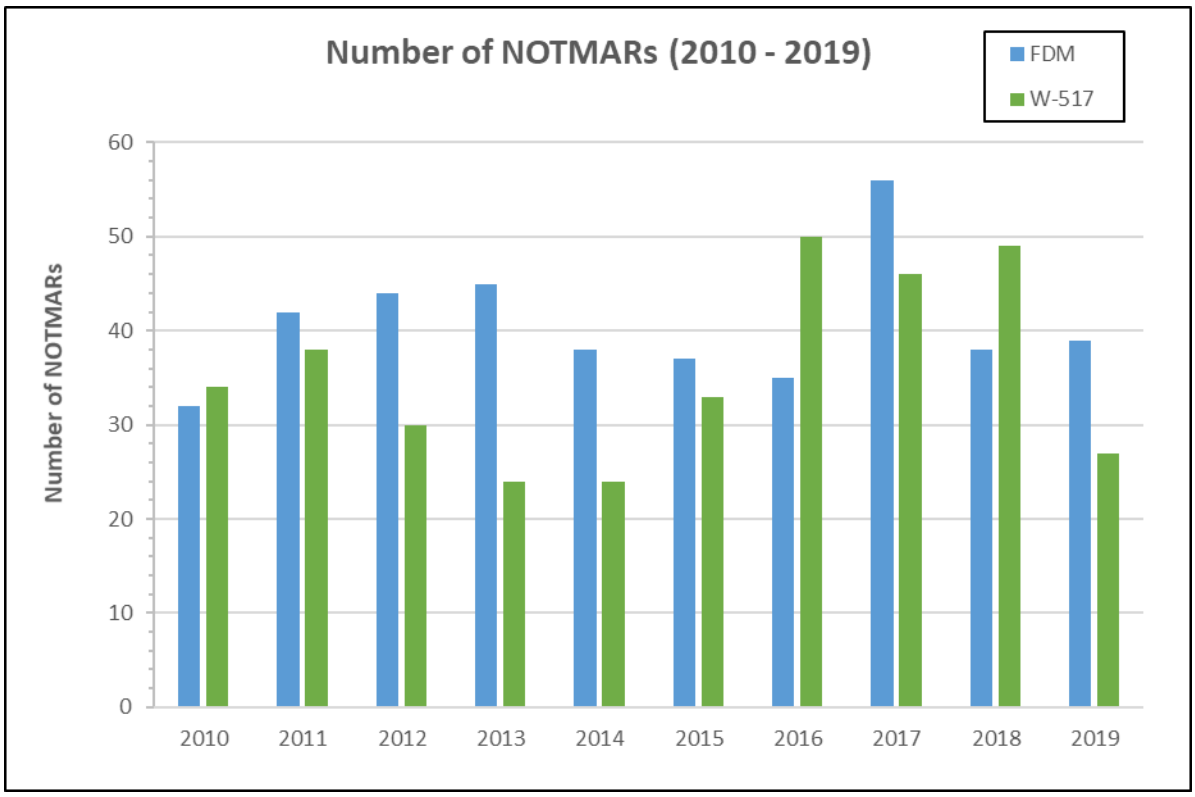

Figure 3.12-3: Number of NOTMARs Issued for FDM and W-517 for the Years 2010 through 2019

The number of days affected by activities occurring at FDM and W-517 has varied over the ten-year period from the years 2010 through 2019 (Figure 3.12-4). The data indicate a slightly increasing trend in the number of affected days for W-517 and potential impacts on accessibility. Overall, the trend appears to be cyclical (increases followed by decreases). However, from the years 2010 through 2014, the average number of days affected was 78, and from 2015 through 2019, the average increased to 103 days, suggesting an upward trend. As noted above, increased use of W-11, W-12, and W-13 may reverse this trend in the coming year.

Access to waters around FDM between 3 and 12 NM was restricted for an average of 159 days per year (peak of 201 in the year 2012), and access to waters under W-517 was restricted for an average of 90 days per year (peak of 136 in the year 2016). Access to waters within 3 NM of FDM is restricted at all times to ensure public safety during military activities using explosive munitions and unexploded ordnance (33 CFR 334, Danger Zone and Restricted Area Regulations). If a restriction or closure is issued for any part of a particular day, then the day was considered to be affected by that closure. When a NOTMAR is issued, it specifies the time of day and the length of time that a particular area is restricted or closed to the public, which can range from a few hours to the entire day.

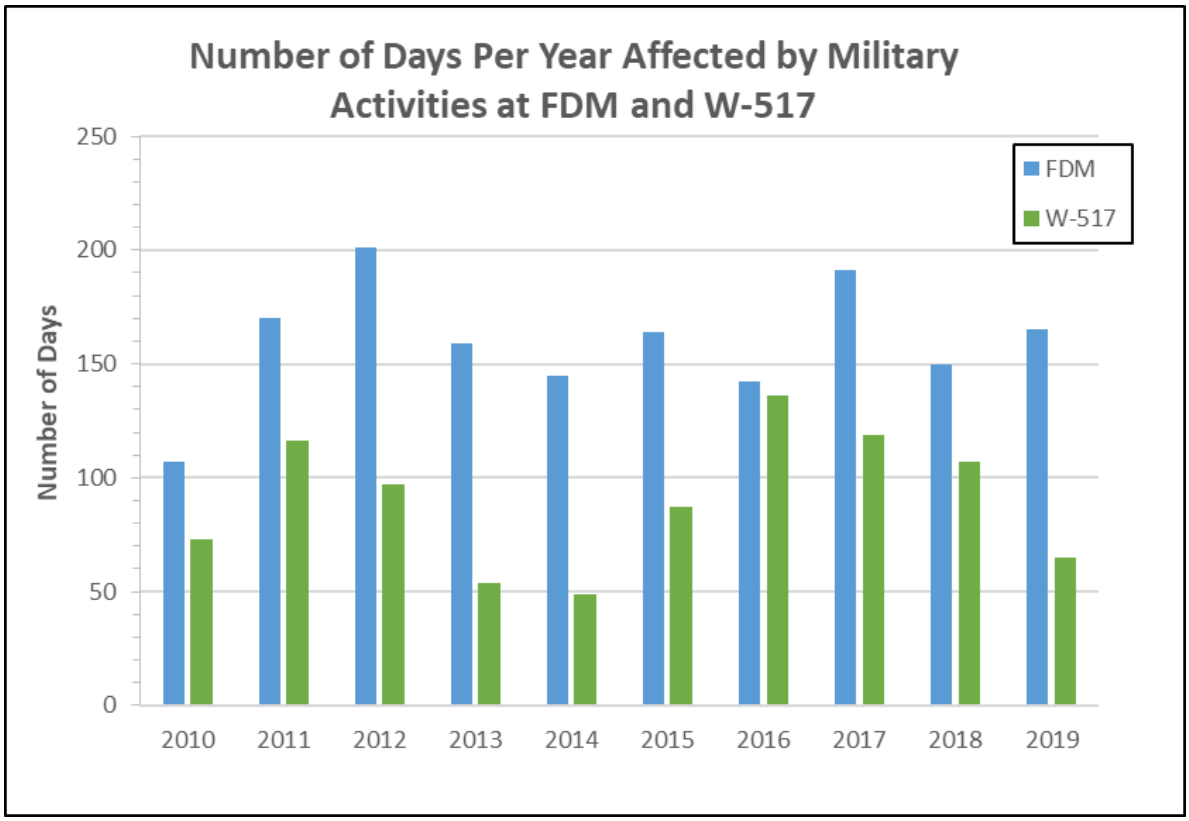

Figure 3.12-4: Number of Days per Year Affected by Military Activities at FDM and W-517

New information on commercial fisheries and tourism was added to Section 3.12.1.2 (Commercial and Recreational Fishing) and Section 3.12.1.3 (Tourism), respectively. While accessibility to popular fishing sites is a factor potentially affecting fishing and tourism, the data and supporting information for both industries indicate that other economic factors are driving current trends and forecasts in both industries (Cuetos-Bueno & Houk, 2014; Weijerman et al., 2016).

The military also requests that the FAA issue NOTAMs to warn the public of upcoming military activities requiring the exclusive use of airspace. Military operating areas and SUA are identified on nautical and aeronautical charts to inform surface vessels and aircraft that military activities occur in the area. When necessary, airspace used by the military is restricted for short periods of time (typically on the order of hours) to cover the timeframes of training and testing activities. The Navy posts NOTAMs when restrictions are in place prior to initiating a training or testing activity, and the military follows standard operating procedures to visually scan an area to ensure that non-participants (i.e., civilian vessels and aircraft) are not present. If non-participants are present, the military delays, moves, or cancels its activity. Public accessibility is no longer restricted once the activity concludes. Refer to Section 2.3.3 (Standard Operating Procedures) of this SEIS/OEIS for additional information on standard operating procedures.

No commercial or recreational activities occur or are permitted on or near FDM, and aircraft and marine vessels are restricted from entering within 3 NM of FDM. Even when live-fire or other potentially hazardous activities are not occurring at FDM, the threat of unexploded ordnance is always present. As with other activities, the Navy posts NOTMARs and NOTAMS at least 72 hours in advance of potentially hazardous training and testing activities at FDM. NOTMARs and NOTAMs may extend restrictions out to

12 NM as needed for certain training and testing activities to ensure the safety and protection of the public and the military. Detailed information on accessibility to areas in the Study Area is presented in Section 3.12.3.1 (Accessibility [to the Ocean and Airspace]) in the 2015 MITT Final EIS/OEIS.

In addition to issuing NOTMARs and NOTAMs to announce scheduled training and testing events, upcoming events are communicated to stakeholders (e.g., Guam and CNMI local mayors, Guam legislators, resources agencies, and fishers) via e-mail distribution developed by Joint Region Marianas (JRM) with stakeholder input. Notices are also sent to the National Oceanic and Atmospheric Administration, local cable channels, and emergency management offices.

Other communication outlets available to the public include the JRM Public Affairs Office, which posts press releases on the JRM website and on the JRM Facebook page (https://www.facebook.com/jrmguam/) (Figure 3.12-5). Interested members of the public can also follow the JRM on Twitter. Posts to the JRM Facebook page activate a Twitter post. Naval Base Guam Public Affairs posts press releases on the Naval Base Guam Facebook page (https://www.facebook.com/USNavalBaseGuam/), and Naval Facilities Engineering Command, Marianas Public Affairs posts press releases on their Facebook page (https://www.facebook.com/navfacmarianas/).

As new communication tools become available, the military will consider their usefulness in communicating important information to the public about training and testing activities. The military will continue to engage the public on issues associated with accessibility to the ocean and airspace within the Study Area.

As presented above, new information relevant to accessibility impacts has become available since publication of the 2015 MITT Final EIS/OEIS (Figure 3.12-3 and Figure 3.12-4) (Cuetos-Bueno & Houk, 2014; Weijerman et al., 2016). However, this information confirms that there has been no appreciable change to the existing environmental conditions as presented in the 2015 MITT Final EIS/OEIS, and the results of the analysis of impacts on accessibility to the ocean and airspace remain valid.

Direct impacts on cruises to the Northern Mariana Islands of Pagan and the island of Maug are not anticipated, because none of the proposed training and testing activities would occur on or near islands north of FDM. The cruise vessel route advertised by the Silversea cruise line (Silversea, 2019), which includes a stop in Saipan, would pass to the west of FDM on the way to Pagan. Considering that the Navy publicizes through multiple outlets when the area around FDM between 3 and 12 NM would be inaccessible, a cruise line, such as Silversea, would be able to plan accordingly to avoid or minimize any potential economic impact.

Upon completion of training and testing activities, restrictions are lifted and commercial and recreational fishers (and other non-military vessels) would be able to return to fish and transit through the area. To help manage competing demands and maintain public access in the Study Area, the military conducts its offshore operations in a manner that reduces restrictions to commercial fisherman. Military ships, fishers, and recreational users operate within the area together, and keep a safe distance between each other. Military participants would relocate as necessary to avoid conflicts with non-participants. The 3 NM area surrounding FDM is the only area designated as a surface danger zone that is permanently inaccessible to the public. The permanent designation is to ensure public safety.

The 2015 MITT EIS/OEIS notes that some training and testing activities may impact commercial and recreational fishing when areas of co-use are made temporarily, or in the case of waters surrounding FDM, permanently inaccessible to ensure the safety of the public. The number of NOTMARs issued from

the years 2010 through 2018 restricting access to waters around FDM peaked in the year 2016, and the number of days affected by activities at FDM was the highest since the year 2012 (Figure 3.12-3, Figure 3.12-4). For W-517, both the number of NOTMARs and the number of days affected peaked in the year 2016. Popular fishing areas in or adjacent to the northern part of W-517 remain accessible when activities are conducted in the southern part of the warning area (Figure 3.12-5). While closure of the entire warning area had been a concern of fishers (Tibbats & Flores, 2012), this accommodation by the military allows areas within W-517 to be open to non-military vessels for fishing and transit to Galvez Bank, Santa Rosa Reef, and White Tuna Banks (see Section 3.12, Socioeconomic Resources, in the 2015 MITT Final EIS/OEIS for details). Considering that restrictions on accessing areas of co-use would continue to be periodic, temporary, and short-term, and other fishing sites in the Study Area would be available to the public, significant impacts on access to ocean areas used for commercial and recreational fishing, tourism, and traditional fishing practices are not anticipated. Individual fishers or tourists who are unaware of a temporary closure may need to change plans abruptly, which could substantially impact that particular trip; however, the overall access by the public to ocean and air space in the Study Area would remain consistent with the level of accessibility in the recent past (see Figure 3.12-3 and Figure 3.12-4), and advance notice of pending closures to areas used by the military will help to avoid or reduce impacts.

As stated in the 2015 MITT Final EIS/OEIS and summarized in this section, the potential impacts on accessibility from the proposed training and testing activities under Alternative 1 would remain consistent with ongoing activities and would not be significant. Traditional fishing practices typically occur in the same general areas as recreational fishing (Allen, 2013), which is close to shore and far from the majority of training and testing activities (with the exception of activities at FDM) that would limit access to an area.

The impacts on traditional fishers would not be disproportionately high in comparison to potential impacts on other fishers, and adverse human health or environmental effects on minority populations and low-income populations would not be disproportionately high in comparison to the general population on Guam and the CNMI. Environmental health risks or safety risks to children would not be disproportionately high compared with the general population.

3.12.2.1.2 Impacts from Limits on Accessibility Under Alternative 2 (Preferred Alternative)

In some cases, under Alternative 2, the number of proposed training and testing events would change as compared to the number of events proposed in the 2015 MITT Final EIS/OEIS (see Tables 2.5-1 and 2.5-2 in this SEIS/OEIS for changes in the number of annual events for specific activities). Only some activities that increased under Alternative 2 have the potential to impact accessibility to areas in the Study Area used by both the military and the public. The activities that increased are identified (highlighted) in Tables 2.5-1 and 2.5-2 and in Appendix F (Training and Testing Activities Matrices) in this SEIS/OEIS. For example, six Gunnery Exercise (Surface-to Air–Large Caliber) activities per year are proposed under Alternative 1, nine are proposed under Alternative 2, and this activity has the potential to limit accessibility.

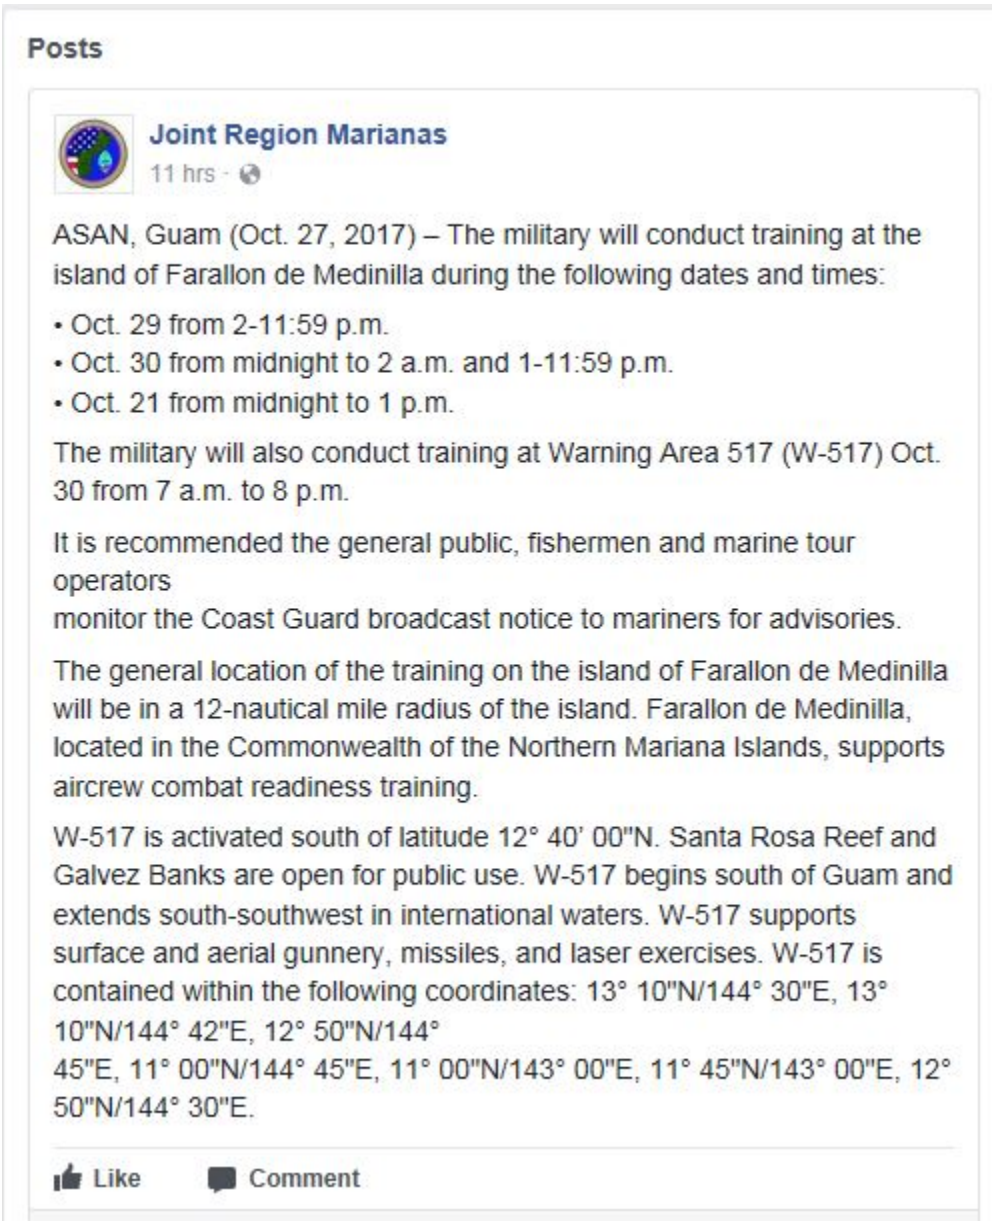

Figure 3.12-5: Joint Region Marianas Facebook Post Announcing Military Training Activities at FDM and W-517

Under Alternative 2, similar to Alternative 1, activities involving the use of aircraft, vessels, or in-water devices may temporarily limit accessibility to areas of the Study Area. Table 3.0-11 in Section 3.0 (Introduction) shows that the number of annual events using aircraft is approximately the same under Alternative 2 as under Alternative 1, while Table 3.0-12 and Table 3.0-13 show that the number of annual events using vessels and in-water devices is only marginally higher under Alternative 2 compared with Alternative 1.

After reviewing the changes in the numbers and types of training and testing activities with the potential to limit accessibility, the Navy determined that potential impacts on accessibility under Alternative 2 would be the same or similar to impacts identified under Alternative 1. Therefore, increases in the

number of events shown in Tables 2.5-1 and 2.5-2 under Alternative 2 would have no appreciable change on the conclusions presented under Alternative 1 and in the 2015 MITT Final EIS/OEIS.

As stated in the 2015 MITT Final EIS/OEIS and summarized in this section, the potential impacts on accessibility from the proposed training and testing activities under Alternative 2 would remain consistent with ongoing activities and activities under Alternative 1 and would not be significant. Traditional fishing practices typically occur in the same general areas as recreational fishing (Allen, 2013), which is close to shore and far from the majority of training and testing activities (with the exception of activities at FDM) that would limit access to an area.

The impacts on traditional fishers would not be disproportionately high in comparison to potential impacts on other fishers, and adverse human health or environmental effects on minority populations and low-income populations would not be disproportionately high in comparison to the general population on Guam and the CNMI. Environmental health risks or safety risks to children would not be disproportionately high compared with the general population.

3.12.2.1.3 Impacts from Limits on Accessibility Under the No Action Alternative

Under the No Action Alternative, the proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Limits on accessibility to the ocean and airspace as described above would be eliminated or reduced. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing training and testing activities as described under the No Action Alternative would reduce impacts on accessibility to areas of co-use, but would not measurably improve access to the ocean and airspace in the Study Area.

Certain limitations on accessing danger zones, restricted areas, and warning areas as described in the 2015 MITT Final EIS/OEIS and in the Code of Federal Regulations would still apply for safety or regulatory reasons (e.g., safety concerns over the presence of unexploded ordnance around FDM). Refer to Code of Federal Regulations, Title 33 (Navigation and Navigable Waters), Part 334 (Danger Zone and Restricted Area Regulations), 33 CFR 165.1401 (Safety Zones), 14 CFR Part 73.1 (Special Use Airspace) for specific regulations regarding these ocean areas and airspace. A more detailed description of danger zones, restricted areas, and special use airspace in the Study Area is provided in Section 3.12.3.1 (Accessibility [to the Ocean and Airspace]) in the 2015 MITT Final EIS/OEIS.

Not conducting the proposed at-sea training and testing activities may have negative impacts on the socioeconomic resources of Guam and the CNMI. The number of jobs and types of jobs available on Guam, and to a lesser extent on the CNMI, may decline. The Navy and Navy personnel are an important and often stabilizing contributor to the local and regional economies. For example, vessels and associated equipment used specifically for training and testing activities would no longer be needed if all training and testing activities ceased. Consequently, the civilian and Navy personnel supporting those activities may be relocated, reassigned, or have to find other employment. The secondary effects from reducing the number of personnel who support at-sea training and testing activities could include a decline in revenue for local businesses frequented by Navy personnel and their families, such as businesses in the food services, retail, and housing sectors.

As described in Section 3.12.1 (Affected Environment), the Navy contributes to the economies of Guam and the CNMI, which includes expenditures associated with at-sea training and testing activities. If a

substantial number of Navy personnel are relocated due to the elimination of training and testing activities, a portion of the 12,800 Navy personnel and their dependents (approximately 8 percent of the population) residing on Guam would potentially be relocated off the island. A reduction in the population and Navy funding for training and testing activities may lessen the ability of military funding to stabilize the economy against fluctuations in the tourism sector. Training activities that use any of the seven vessels assigned to Saipan would no longer be conducted. This may reduce the need for or usage of one or more of the vessels, leading to a reduction in the funding expended to maintain the vessels at Saipan. Based on these two examples, the economies and social communities on Guam and the CNMI would be impacted to some degree if the proposed at-sea training and testing activities were not conducted.

3.12.2.2 Airborne Acoustics

3.12.2.2.1 Impacts from Airborne Acoustic Stressors Under Alternative 1

Training and testing activities that would increase under Alternative 1 and that use vessels, aircraft, or weapons firing would potentially increase airborne acoustics in certain areas of the Study Area that are used by the military (Tables 2.5-1 and 2.5-2). However, decreases in the number of training and testing events occurring in areas of co-use would potentially decrease airborne acoustics in those areas. Only some training and testing activities that either increased or decreased have the potential to generate airborne acoustics and require further analysis to supplement the analysis in the 2015 MITT Final EIS/OEIS.

The activities that changed (i.e., increased or decreased) are identified (highlighted) in Tables 2.5-1 and 2.5-2 and in Appendix F (Training and Testing Activities Matrices) in this SEIS/OEIS. The two tables and Appendix F were used together to identify which of the activities that either increased or decreased have the potential to generate airborne acoustics in the Study Area. For example, five GUNEX (Surface-to-Air–Large Caliber) activities per year were proposed in the 2015 MITT Final EIS/OEIS, and six were proposed under Alternative 1 in this SEIS/OEIS (Table 2.5-1 in Chapter 2, Description of Proposed Action and Alternatives). Referring to Table F-1 (Stressors by Training Activity) in Appendix F (Training and Testing Activities Matrices), the activity GUNEX (Surface-to-Air) is identified with a check mark as having the potential to generate airborne acoustics (listed as a socioeconomic stressor) in the Study Area.

As shown in Appendix F (Training and Testing Activities Matrices), the majority of the proposed training and testing activities generate airborne acoustics, which supports using the number of annual events proposed under each alternative as a metric to compare impacts. Generally, activities involving the use of aircraft, vessels, or explosive munitions may generate airborne acoustics detectable by the public in areas of the Study Area where military and civilian activities occur in close proximity. Table 3.0-11 shows that the number of annual events using aircraft would decrease under Alternative 1 compared to totals in the 2015 MITT Final EIS/OEIS, and Table 3.0-16 shows that the use of nearly all types of explosive munitions would also decrease under Alternative 1.

After reviewing the changes in the numbers and types of proposed training and testing activities with the potential to generate airborne acoustics, the Navy determined that potential impacts from airborne acoustics on socioeconomic resources would not be substantially different from the 2015 MITT Final EIS/OEIS. Therefore, the analysis, supplemented below, from the 2015 MITT Final EIS/OEIS remains valid.

Loud noises generated from training and testing activities such as weapons firing, in-air explosions, and aircraft transiting have the potential to disrupt recreational activities such as wildlife viewing, boating,

fishing, and scuba diving. In addition to local residents, tourists participate in these activities in the Study Area. Encountering loud noises, particularly those that occur suddenly and nearby, could interfere with the enjoyment of several types of recreational activities. Disturbance from continuous, albeit less intense, noises could also affect the enjoyment of an activity. Airborne noises from military activities would occur on a temporary basis and only when weapons firing and in-air explosions occur and as aircraft transit through an area. Training and testing activities involving weapons firing and in-air explosions would only occur when the military can confirm the area is clear of non-participants (e.g., the public). This would reduce the likelihood that noise from these activities, which are taking place far from non-participants, would disturb residents or tourists engaged in recreational activities on the water. Furthermore, most training and testing activities involving aircraft occur more the 12 NM from shore and those that occur closer to shore are typically at least 3 NM offshore (with the exception of activities at FDM). Noises generated from training and testing activities would occur far offshore and at a great distance from the recreational activities that typically occur closer to shore, reducing the disturbing effect of any perceived noise.

Noise from aircraft overflights would occur most frequently around Guam, the busiest airport in the Study Area, during takeoff and landing. Air Traffic Control Assigned Airspace is used for training and testing activities in the Study Area. The airspace referred to as Air Traffic Control Assigned Airspace-6 overlays Guam, Saipan, Tinian, and Rota and has a lower altitude limit of 39,000 ft. Aircraft at that altitude (or higher) are not likely to generate noise at sea level that would disrupt recreational activities. Revenue from tourism and recreational activities is not expected to be impacted by airborne noise. Refer to Section 3.12.2.1.2 (Air Traffic) of the 2015 MITT Final EIS/OEIS for more information on the different types of special use airspace in the Study Area and potential socioeconomic impacts from airborne noise.

There has been no appreciable change to the existing environmental conditions as presented in the 2015 MITT Final EIS/OEIS, and the results of the analysis of impacts from airborne noise on recreational activities and tourism remain the same. Therefore, no impacts on tourism would be anticipated because (1) most military training occurs well out to sea, while most tourism and recreational activities occur nearshore; (2) military aircraft generally depart from Andersen Air Force Base and travel north well away from tourist and residential areas; and (3) training and testing activities producing airborne noise are normally short term and temporary. Therefore, airborne noise impacts on tourism would be negligible.

As stated in the 2015 MITT Final EIS/OEIS and summarized in this section, the potential impacts from airborne acoustics from the proposed training and testing activities under Alternative 1 would remain consistent with ongoing activities and would not be significant. Traditional fishing practices typically occur in the same general areas as recreational fishing (Allen, 2013), which is close to shore and far from the majority of training and testing activities that generate higher levels of airborne acoustics (with the exception of activities at FDM).

The impacts on traditional fishers would not be disproportionately high in comparison to potential impacts on other fishers, and adverse human health or environmental effects on minority populations and low-income populations would not be disproportionately high in comparison to the general population on Guam and the CNMI. Environmental health risks or safety risks to children would not be disproportionately high compared with the general population.

3.12.2.2.2 Impacts from Airborne Acoustic Stressors Under Alternative 2 (Preferred Alternative)

In some cases, under Alternative 2, the number of proposed training and testing events would change as compared to the number of events proposed in the 2015 MITT Final EIS/OEIS (see Tables 2.5-1 and 2.5-2 in this SEIS/OEIS for changes in the number of annual events for specific activities).Only some activities that increased under Alternative 2 have the potential to generate airborne acoustics that would be detectable by the public. The activities that increased are identified (highlighted) in Tables 2.5-1 and 2.5-2 and in Appendix F (Training and Testing Activities Matrices) in this SEIS/OEIS. For example, six GUNEX (Surface-to Air – Large Caliber) activities per year are proposed under Alternative 1, and nine are proposed under Alternative 2, and this activity would generate airborne acoustics that may be detectable by the public.

Under Alternative 2, activities involving the use of aircraft, vessels, or explosive munitions may generate airborne acoustics detectable by the public in areas of the Study Area where military and civilian activities occur in close proximity. Table 3.0-11 shows that the number of annual events using aircraft slightly increases under Alternative 2 compared to Alternative 1, and Table 3.0-12 shows that activities using vessels would increase marginally (<10 percent) under Alternative 2. The numbers of the different types of explosive munitions used under Alternative 2 are either the same or similar to totals under Alternative 1 (Table 3.0-16).

After reviewing the changes in the numbers and types of training and testing activities with the potential to increase airborne acoustics, the Navy determined that potential impacts from airborne acoustics under Alternative 2 would be the same or similar to impacts identified under Alternative 1. Therefore, increases under Alternative 2 would have no appreciable change on the conclusions presented under Alternative 1 and in the 2015 MITT Final EIS/OEIS.

As stated in the 2015 MITT Final EIS/OEIS and summarized in this section, the potential impacts from airborne acoustics from the proposed training and testing activities under Alternative 2 would remain consistent with ongoing activities and activities under Alternative 1 and would not be significant. Traditional fishing practices typically occur in the same general areas as recreational fishing (Allen, 2013), which is close to shore and far from the majority of training and testing activities that generate higher levels of airborne acoustics (with the exception of activities at FDM).

The impacts on traditional fishers would not be disproportionately high in comparison to potential impacts on other fishers, and adverse human health or environmental effects on minority populations and low-income populations would not be disproportionately high in comparison to the general population on Guam and the CNMI. Environmental health risks or safety risks to children would not be disproportionately high compared with the general population.

3.12.2.2.3 Impacts from Airborne Acoustic Stressors Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Disturbances from airborne acoustic stressors as listed above would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing training and testing activities would result in fewer disturbances from airborne acoustics within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the

potential for disturbances from airborne acoustics, but would not measurably change the frequency or severity of disturbances from airborne acoustics experienced by the public in the Study Area.

Not conducting the proposed at-sea training and testing activities may have negative impacts on the socioeconomic resources of Guam and the CNMI. The number of jobs and types of jobs available on Guam and to a lesser extent on the CNMI may decline. The Navy and Navy personnel are an important and often stabilizing contributor to the local and regional economies. For example, vessels and associated equipment used specifically for training and testing activities would no longer be needed if all at-sea training and testing activities ceased. Consequently, the civilian and Navy personnel supporting those activities may be relocated, reassigned, or have to find other employment. The secondary effects from reducing the number of personnel who support at-sea training and testing activities could include a decline in revenue for local businesses frequented by Navy personnel and their families, such as businesses in the food services, retail, and housing sectors.

As described in Section 3.12.1 (Affected Environment), the Navy contributes to the economies of Guam and the CNMI, which includes expenditures associated with at-sea training and testing activities. If a substantial number of Navy personnel are relocated due to the elimination of training and testing activities, a portion of the 12,800 Navy personnel and their dependents (approximately 8 percent of the population) residing on Guam would potentially be relocated off the island. A reduction in the population and Navy funding for training and testing activities may lessen the ability of military funding to stabilize the economy against fluctuations in the tourism sector. Training activities that use any of the seven vessels assigned to Saipan would no longer be conducted. This may reduce the need for or usage of one or more of the vessels, leading to a reduction in the funding expended to maintain the vessels at Saipan. Based on these two examples, the economies and social communities on Guam and the CNMI would be impacted to some degree if the proposed at-sea training and testing activities were not conducted.

3.12.2.3 Physical Disturbance and Strike Stressors

3.12.2.3.1 Impacts from Physical Disturbance and Strike Stressors Under Alternative 1

Training and testing activities that would increase under Alternative 1 and that use vessels, aircraft, munitions, and military expended materials would potentially increase the risk of physical disturbance and strike in certain areas of the Study Area that are used by both the military and the public (Tables 2.5-1 and 2.5-2). However, decreases in the number of training and testing events occurring in areas of co-use would potentially decrease the potential for physical disturbance and strike in those areas. Only some training and testing activities that either increased or decreased have the potential for physical disturbance and strike and require further analysis to supplement the analysis in the 2015 MITT Final EIS/OEIS.

The activities that changed (i.e., increased or decreased) are identified (highlighted) in Tables 2.5-1 and 2.5-2 and in Appendix F (Training and Testing Activities Matrices) in this SEIS/OEIS. The two tables and Appendix F were used together to identify which of the activities that either increased or decreased have the potential to result in a physical disturbance or strike in the Study Area. For example, five GUNEX (Surface-to-Air – Large Caliber) activities per year were proposed in the 2015 MITT Final EIS/OEIS, and six were proposed under Alternative 1 in this SEIS/OEIS (Table 2.5-1 in Chapter 2, Description of Proposed Action and Alternatives). Referring to Table F-1 (Stressors by Training Activity) in Appendix F (Training and Testing Activities Matrices), the activity GUNEX (Surface-to-Air) is identified

with a check mark as having the potential for physical disturbance and strike (listed as a socioeconomic stressor) in the Study Area.

As shown in Appendix F (Training and Testing Activities Matrices), the majority of the proposed training and testing activities use vessels, in-water devices, aircraft, munitions, or military expended materials and could result in a physical disturbance or strike, which supports using the number of annual events proposed under each alternative as a metric to compare impacts. Table 3.0-11 shows that the number of events using aircraft would decrease by about 10 percent under Alternative 1 compared to totals in the 2015 MITT Final EIS/OEIS; however, Table 3.0-12 and Table 3.0-13 show that the number of annual events using vessels and in-water devices would increase by about 15 and 4 percent, respectively, under Alternative 1 compared to totals in the 2015 MITT Final EIS/OEIS. Table 3.0-15 shows that the use of some non-explosive practice munitions would increase over the totals in the 2015 MITT Final EIS/OEIS, while other non-explosive practice munitions would decrease; Table 3.0-16 shows that the use of nearly all types of explosive munitions would also decrease under Alternative 1. Most types of other military expended materials would decrease under Alternative 1 (Table 3.0-15).

After reviewing the changes in the numbers and types of proposed training and testing activities with the potential for physical disturbance and strike and the numbers of munitions and other military expended materials that would be used, the Navy determined that potential impacts from physical disturbance and strike on socioeconomic resources would not be substantially different from the 2015 MITT Final EIS/OEIS. Therefore, the analysis, supplemented below, from the 2015 MITT Final EIS/OEIS remains valid.

The evaluation of impacts on socioeconomic resources from physical disturbance and strike stressors focuses on direct physical encounters or collisions with objects moving through the water or air (e.g., vessels, aircraft, unmanned devices, and towed devices), dropped or fired into the water (non-explosive practice munitions, other military expended materials, and ocean bottom deployed devices), or resting on the ocean floor (anchors, mines, targets) that may damage or encounter civilian equipment. Physical encounters that damage equipment and infrastructure could disrupt the collection (e.g., of fisheries resources) and transport of products, which could impact industry revenue or operating costs. Socioeconomic resources potentially impacted by encounters with military vessels, devices, and objects include commercial transportation and shipping, commercial and recreational fishing, traditional fishing practices, and tourism.

The majority of commercial and recreational fishing, traditional fishing practices, and tourism in the Study Area takes place in nearshore waters (less than 3 NM from shore), where, with the exception of training activities at FDM, the military conducts limited training and testing involving munitions or other expended materials. The permanent danger zone extending out to 3 NM from shore around FDM is in place to ensure that the public is not at risk from a physical disturbance or strike while an activity is being conducted and to ensure the public is not at risk from any unexploded ordnance located in nearshore waters around the island. Therefore, most recreational fishing, traditional fishing practices, and tourism activities would occur far away from physical disturbance and strike stressors.

Larger commercial fishing vessels are more likely to go beyond 3 NM and approach areas where the military trains and tests and could be affected by physical disturbances or strikes. The military's standard operating procedures, which are discussed in Section 2.3.3 (Standard Operating Procedures) of this SEIS/OEIS, includes ensuring that an area is clear of all non-participating vessels before training and

testing activities take place, which includes commercial fishing vessels (refer to Section 3.12.3.3, Physical Disturbance and Strike, of the 2015 MITT Final EIS/OEIS for detailed analysis).

Commercial shipping vessels transport goods internationally and would be expected to transit through offshore waters en route to domestic and foreign ports. Shipping vessels follow established routes which are avoided by the military during training and testing activities, and both military and civilian vessels in proximity to each other are expected to communicate their positions. In addition, the military provides advance notification of training and testing activities to the public through NOTMARs and other means of communication as described in Section 3.12.2.1 (Accessibility [to the Ocean and Airspace]). For these reasons, a direct strike or collision with a shipping vessel is unlikely.

Additional information and analysis of physical disturbance and strike stressors and the potential for interactions with commercial fishing vessels and gear is described in Section 3.12.3.3 (Physical Disturbance and Strike) of the 2015 MITT Final EIS/OEIS.

New information relevant to physical disturbance and strike impacts has become available since publication of the 2015 MITT Final EIS/OEIS. There has been no appreciable change to the existing environmental conditions as presented in the 2015 MITT Final EIS/OEIS, and the results of the analysis of impacts from physical disturbance and strike on commercial transportation and shipping, commercial and recreational fishing, traditional fishing practices, and tourism remain the same. The advanced public release of NOTMARs and other public notices would inform the public of upcoming activities, and enable them to plan to avoid the area.

The Navy would implement mitigation to avoid or reduce impacts from physical disturbance and strike stressors on seafloor resources in mitigation areas throughout the Study Area (see Section 5.4.1, Mitigation Areas for Seafloor Resources). The mitigation areas will help avoid or reduce potential impacts on shallow-water coral reefs, live hard bottom, artificial reefs, and shipwrecks, which are valuable assets for the snorkeling, diving, and fishing industries. Considering the size of the Navy's Study Area, the wide distribution of military expended materials over this large area, and implementation of standard operating procedures and mitigation, impacts from physical disturbances and strikes on commercial and recreational fishing, traditional fishing practices, and tourism would be negligible under Alternative 1. Refer to Section 2.3.3 (Standard Operating Procedures) of this SEIS/OEIS for additional information on the Navy's standard operating procedures and Chapter 5 (Mitigation) for information on proposed mitigation measures.

As stated in the 2015 MITT Final EIS/OEIS and summarized in this section, the potential impacts from a potential physical disturbance and strike from the proposed training and testing activities under Alternative 1 would remain consistent with ongoing activities and would not be significant. Traditional fishing practices typically occur in the same general areas as recreational fishing (Allen, 2013), which is close to shore and far from the majority of training and testing activities with the potential to result in a physical disturbance and strike (with the exception of activities at FDM). Therefore, there would be no disproportionately high and adverse human health or environmental effects on any minority populations and low-income populations or disproportionately high environmental health risks or safety risks to children.

3.12.2.3.2 Impacts from Physical Disturbance and Strike Stressors Under Alternative 2 (Preferred Alternative)

In some cases, under Alternative 1, the number of proposed training and testing events would change as compared to the number of events proposed in the 2015 MITT Final EIS/OEIS (see Tables 2.5-1 and 2.5-2 in this SEIS/OEIS for changes in the number of annual events for specific activities).Only some activities

that increased under Alternative 2 have the potential to increase the risk of physical disturbance and strike in certain areas of the Study Area that are used by both the military and the public. The activities that increased are identified (highlighted) in Tables 2.5-1 and 2.5-2 and in Appendix F (Training and Testing Activities Matrices). For example, six GUNEX (Surface-to Air–Large Caliber) activities per year are proposed under Alternative 1, nine are proposed under Alternative 2, and this activity has the potential to result in a physical disturbance or strike.

As shown in Appendix F (Training and Testing Activities Matrices), the majority of the proposed training and testing activities use vessels, in-water devices, aircraft, munitions, or military expended materials and could result in a physical disturbance or strike, which supports using the number of annual events proposed under each alternative as a metric to compare impacts. Table 3.0-11 shows that the number of annual events using aircraft is approximately the same under Alternative 2 as under Alternative 1, while Table 3.0-12 and Table 3.0-13 show that the number of events using vessels and in-water devices is only marginally higher under Alternative 2 compared with Alternative 1. Table 3.0-14 shows that the use of some non-explosive practice munitions would increase under Alternative 2 compared to totals under Alternative 1; the numbers of the different types of explosive munitions used under Alternative 2 are either the same or similar to totals under Alternative 1 (Table 3.0-16). Five out of the 10 different types of other military expended materials shown in Table 3.0-15 would also increase under Alternative 2; however, the increases are not substantial.

After reviewing the changes in the numbers and types of training and testing activities with the potential to increase the probability of a physical disturbance and strike, the Navy determined that potential impacts from physical disturbance and strike under Alternative 2 would be the same or similar to impacts identified under Alternative 1. Therefore, increases under Alternative 2 would have no appreciable change on the conclusions presented under Alternative 1 and in the 2015 MITT Final EIS/OEIS.

As stated in the 2015 MITT Final EIS/OEIS and summarized in this section, the potential impacts from a potential physical disturbance and strike from the proposed training and testing activities under Alternative 2 would remain consistent with ongoing activities and activities under Alternative 1 and would not be significant. Traditional fishing practices typically occur in the same general areas as recreational fishing (Allen, 2013), which is close to shore and far from the majority of training and testing activities with the potential to result in a physical disturbance and strike (with the exception of activities at FDM).

The impacts on traditional fishers would not be disproportionately high in comparison to potential impacts on other fishers, and adverse human health or environmental effects on minority populations and low-income populations would not be disproportionately high in comparison to the general population on Guam and the CNMI. Environmental health risks or safety risks to children would not be disproportionately high compared with the general population.

3.12.2.3.3 Impacts from Physical Disturbance and Strike Stressors Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Physical disturbance and strike stressors as listed above would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing training and testing activities would result in fewer physical disturbance and strike stressors within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for physical disturbances and strikes, but would not measurably change the number of times the public is exposed to physical disturbance and strike stressors in the Study Area.

Not conducting the proposed at-sea training and testing activities may have negative impacts on the socioeconomic resources of Guam and the CNMI. The number of jobs and types of jobs available on Guam and to a lesser extent on the CNMI may decline. The Navy and Navy personnel are an important and often stabilizing contributor to the local and regional economies. For example, vessels and associated equipment used specifically for at-sea training and testing activities would no longer be needed if all at-sea training and testing activities ceased. Consequently, the civilian and Navy personnel supporting those activities may be relocated, reassigned, or have to find other employment. The secondary effects from reducing the number of personnel who support at-sea training and testing activities could include a decline in revenue for local businesses frequented by Navy personnel and their families, such as businesses in the food services, retail, and housing sectors.

As described in Section 3.12.1 (Affected Environment), the Navy contributes to the economies of Guam and the CNMI, which includes expenditures associated with at-sea training and testing activities. If a substantial number of Navy personnel are relocated due to the elimination of training and testing activities, a portion of the 12,800 Navy personnel and their dependents (approximately 8 percent of the population) residing on Guam would potentially be relocated off the island. A reduction in the population and Navy funding for training and testing activities may lessen the ability of military funding to stabilize the economy against fluctuations in the tourism sector. Training activities that use any of the seven vessels assigned to Saipan would no longer be conducted. This may reduce the need for or usage of one or more of the vessels, leading to a reduction in the funding expended to maintain the vessels at Saipan. Based on these two examples, the economies and social communities on Guam and the CNMI would be impacted to some degree if the proposed at-sea training and testing activities were not conducted.

3.12.2.4 Secondary Stressors

Secondary stressors resulting in indirect impacts on socioeconomic resources are discussed in Section 3.12.3.4 (Secondary Impacts from Availability of Resources) of the 2015 MITT Final EIS/OEIS. A secondary stressor, as defined in this section, is a stressor that has the potential to affect a socioeconomic resource as a result of a direct effect on another non-socioeconomic resource. For example, if a training activity has the potential to affect certain fish species, and those same fish are part of an economically important fishery, then the effect of the stressor on those fish species could have an indirect, or secondary, effect on the socioeconomic resource of commercial fishing.

3.12.2.4.1 Secondary Impacts from Availability of Resources Under Alternative 1 and Alternative 2 (Preferred Alternative)

The secondary stressor “resource availability” pertains to the potential for loss of fisheries resources, including some invertebrates, within the Study Area, which is relevant to commercial, recreational, and traditional fishing practices as well as tourism. Additionally, impacts on marine mammal populations would have the potential to impact revenue for whale watching businesses if a substantial number of whales were to leave the area or not return to areas where they have been commonly seen. Analysis in Sections 3.4 (Marine Mammals), 3.8 (Marine Invertebrates), and 3.9 (Fishes) determined, however, that

no population-level impacts on marine species are anticipated from the proposed training and testing activities. Those who consume fish and shellfish on a regular basis have also expressed concerns over bioaccumulation of potentially toxic chemicals released from corroding munitions and other expended materials associated with training and testing activities. Analysis presented in Section 3.1 (Sediments and Water Quality) shows that there is no significant toxicity to most marine species from munitions constituents at concentrations on the order of parts per billion, which is typical of sites where munitions have resided for decades, and only in close proximity to a corroding munition (i.e., 1–2 m). At these concentrations, toxicity studies indicate that munitions are unlikely to have an adverse effect on marine species at the population and community level. Specifically for explosives, the constituent chemical compounds that make up the explosive materials are not considered to be the types of compounds to bioaccumulate in the food chain. Scientists who study bioaccumulation, rate the likelihood that a substance would bioaccumulate in a particular food chain by assigning it a bioaccumulation factor. The factor values for constituent compounds of explosives are less than 14 ml/g (for whole organisms), which is more than two orders of magnitude lower than the 5,000 ml/g threshold defined to indicate that a compound has the potential for bioaccumulation (Lotufo, 2018). For these reasons, there would be no secondary impacts on commercial or recreational fishing, traditional fishing practices, or tourism in the Study Area from the use of explosives under Alternative 1 or Alternative 2.

As stated in the 2015 MITT Final EIS/OEIS and summarized in this section, the secondary impacts from the proposed training and testing activities under Alternative 1 and Alternative 2 would remain consistent with ongoing activities and would not be significant. Traditional fishing practices typically occur in the same general areas as recreational fishing (Allen, 2013), which is close to shore and far from the majority of training and testing activities, with the exception of activities at FDM.

The impacts on traditional fishers would not be disproportionately high in comparison to potential impacts on other fishers, and adverse human health or environmental effects on minority populations and low-income populations would not be disproportionately high in comparison to the general population on Guam and the CNMI. Environmental health risks or safety risks to children would not be disproportionately high compared with the general population.

3.12.2.4.2 Secondary Impacts from Availability of Resources Under the No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Secondary stressors impacting resource availability as listed above would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing training and testing activities would result in fewer secondary stressors from the availability of resources within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for secondary stressors, but would not measurably improve the availability of resources associated with secondary impacts on socioeconomic resources in the Study Area.

Not conducting the proposed at-sea training and testing activities may have negative impacts on the socioeconomic resources of Guam and the CNMI. The number of jobs and types of jobs available on Guam and to a lesser extent on the CNMI may decline. The Navy and Navy personnel are an important and often stabilizing contributor to the local and regional economies. For example, vessels and

associated equipment used specifically for at-sea training and testing activities would no longer be needed if all at-sea training and testing activities ceased. Consequently, the civilian and Navy personnel supporting those activities may be relocated, reassigned, or have to find other employment. The secondary effects from reducing the number of personnel who support at-sea training and testing activities could include a decline in revenue for local businesses frequented by Navy personnel and their families, such as businesses in the food services, retail, and housing sectors.

As described in Section 3.12.1 (Affected Environment), the Navy contributes to the economies of Guam and the CNMI, which includes expenditures associated with at-sea training and testing activities. If a substantial number of Navy personnel are relocated due to the elimination of training and testing activities, a portion of the 12,800 Navy personnel and their dependents (approximately 8 percent of the population) residing on Guam would potentially be relocated off the island. A reduction in the population and Navy funding for training and testing activities may lessen the ability of military funding to stabilize the economy against fluctuations in the tourism sector. Training activities that use any of the seven vessels assigned to Saipan would no longer be conducted. This may reduce the need for or usage of one or more of the vessels, leading to a reduction in the funding expended to maintain the vessels at Saipan. Based on these two examples, the economies and social communities on Guam and the CNMI would be impacted to some degree if the proposed at-sea training and testing activities were not conducted.

3.12.3 Public Comments

The public raised a number of concerns during the scoping period about socioeconomic resources and environmental justice. The issues are summarized in the list below. Comments received from the public during the Draft SEIS/OEIS commenting period on the topics of socioeconomic resources and environmental justice are responded to in Appendix K (Public Comment Responses).

- **Restricting the ability of American citizens to move between islands to fish, recreate, or for general travel –** Access to certain areas of the Study Area is restricted during potentially hazardous training and testing activities to ensure the safety of the public and military personnel. Most areas (with the notable exception of the 3 NM danger zone around FDM) are only restricted on a temporary basis and are accessible to the public when not in use by the military. See Section 3.12.2.1 (Commercial Transportation and Fishing) and 3.12.3.1 (Accessibility [to the Ocean and Airspace]) in the 2015 MITT Final EIS/OEIS.
- **Concerns regarding negative effects of sonar testing on swimming and diving in the waters off Guam and the CNMI –** The Navy follows established standard operating procedures when conducting training and testing activities with sonar to ensure that swimmers, divers, and any anyone else who might be in the water are safe (see Section 2.3.3, Standard Operating Procedures). The Navy avoids using sonar near popular swimming and diving sites. See Section 3.12.2.1 (Accessibility [to the Ocean and Airspace]) and Section 3.12.2.4 (Tourism) in the in the 2015 MITT Final EIS/OEIS. Also, refer to Section 3.13 (Public Health and Safety) for information on Navy procedures for protecting swimmers and divers.
- **Improve safety for fishermen by issuing NOTMARs in advance of military activities and posting NOTMARs at local marinas for boaters to view and be warned –** The Navy requests that the U.S. Coast Guard issues NOTMARs to make fishers and other members of the public aware of upcoming training and testing activities that would limit public access to areas of the Study Area. The Navy continues to search for new ways to communicate important information to the public

and now posts information about upcoming closures to several Navy Facebook pages. See Section 3.12.2.1 (Commercial Transportation and Shipping) and 3.12.3.1 (Accessibility [to the Ocean and Airspace]) in the 2015 MITT Final EIS/OEIS. Also, refer to Section 3.13 (Public Health and Safety) for information on Navy procedures for protecting mariners.

- **Request additional and more frequent NOTMARs during military training (e.g., broadcast every two hours, posters at boat harbors, Facebook, and direct communication with fishers) –** The Navy requests that the U.S. Coast Guard issues NOTMARs to make fishers and other members of the public aware of upcoming military activities that would limit public access to areas of the Study Area. In addition to posting NOTMARs, emails are sent to Guam and CNMI local mayors, Guam legislators, resources agencies, and fishers. The distribution was developed by JRM and local stakeholders. In addition, notices are sent to the National Oceanic and Atmospheric Administration, local cable channels, and emergency management offices. The Navy continues to search for new ways to communicate important information to the public and now posts information about upcoming closures to several Navy Facebook pages. See Section 3.12.2.1 (Commercial Transportation and Shipping) and 3.12.3.1 (Accessibility [to the Ocean and Airspace]) in the 2015 MITT Final EIS/OEIS.
- **Training and testing activities disturbing pelagic and economically important fish and causing them to leave the Study Area –** The analysis in Section 3.9 (Fishes) concludes that there would be no population level effects on any fish species, including economically important species. See Section 3.12.2.1 (Accessibility [to the Ocean and Airspace]) and Section 3.12.2.4 (Secondary Stressors). Also refer to Sections 3.8 (Marine Invertebrates) and 3.9 (Fishes) in this SEIS/OEIS and in the 2015 MITT Final EIS/OEIS for detailed analysis explaining why population level effects are not likely to occur.
- **Direct and cumulative impacts on recreational and commercial fishing and transport between the islands due to the location of restricted areas –** Impacts on commercial and recreational fishing and transportation between islands are not expected to have substantial socioeconomic impacts on recreational and commercial fishing in the region. Upon completion of training and testing activities, restrictions on certain areas (e.g., Apra Harbor small arms firing range) are lifted and fishers would be able to return to fish and transit through the area. To help manage competing demands and maintain public access in the Study Area, the military conducts its offshore operations in a manner that reduces restrictions on commercial fishing. Military vessels, fishers, and recreational users operate within the area together, and keep a safe distance between each other. Military participants would relocate as necessary to avoid conflicts with non-participants. Only specific areas within Study Area have been designated as danger zones or restricted areas. See Section 3.12.2.1 (Commercial Transportation and Shipping) and 3.12.3.1 (Accessibility [to the Ocean and Airspace]) in the 2015 MITT Final EIS/OEIS. Also See Chapter 4 (Cumulative Impacts) for a discussion on potential cumulative impacts from past, present, and future Navy and other military activities in the region occurring simultaneously with civilian activities.
- **Socioeconomic effects on recreational and traditional fishers from limiting access to fishing sites, specifically because of restricted areas –** Access to certain areas of the Study Area is restricted during potentially hazardous training and testing activities to ensure the safety of the public and military personnel. Most areas (with the notable exception of the 3 NM danger zone around FDM) are only restricted on a temporary basis and are accessible to the public when not

in use by the military. The Navy understands that individual fishers may be temporarily impacted by a particular event. The Navy will continue to communicate with the public through multiple means to alert fishers and other members of the public of upcoming activities that may limit access to fishing sites. Monitoring NOTMARs and other announcements for scheduled training and testing activities should avoid any conflicts and reduce socioeconomic impacts on fishers. See Section 3.12.2.1 (Accessibility [to the Ocean and Airspace]). See also Section 3.12.3.1.1.2 (Commercial and Recreational Fishing) and Section 3.12.3.1.1.3 (Subsistence Use) in the 2015 MITT Final EIS/OEIS.

- **Loss of income and revenue from loss of access to prime fishing grounds around FDM with the expansion of the restricted area around FDM –** Access to certain areas of the Study Area is temporarily restricted during potentially hazardous training and testing activities to ensure the safety of the public and military personnel. Areas within in 3 NM of FDM have been permanently restricted to maintain public safety. Even when hazardous activities are not occurring at FDM, the potential occurrence of unexploded ordnance in waters surrounding the island is a constant threat to public safety. Transiting between Guam, Saipan, Tinian, and Rota to islands located north of FDM (e.g., the Islands Unit) would potentially be impacted by designating a 12 NM danger zone around the FDM and limiting access to the area when the range is in use. A study conducted by the Pacific Islands Fisheries Science Center on fishing activity in the Islands Unit of the Marianas Trench Marine National Monument reported that vessels have historically traveled from the southern Mariana Islands to the Islands Unit (defined as the islands of Uracas, Maug, and Asuncion) an average of 3.8 times per year over the 30-year period from the years 1979 through 2009 (Kotowicz & Richmond, 2013). Travel to other islands north of FDM (e.g., Anatahan and Pagan) may be more frequent; however, the study did not address islands located south of the Islands Unit. Considering that trips between the populated island south of FDM and the Islands Unit would be relatively infrequent, the probability of military activities that temporarily limit access to ocean areas within 12 NM of FDM interfering with trips to the Islands Unit would be low. The most direct route between Saipan (the northernmost populated island) and Anatahan (the closest island north of FDM) passes more than 12 NM west of FDM. Furthermore, the military will continue to announce when FDM is not in use in addition to notifying mariners of planned activities via NOTMARs (issued by the U.S. Coast Guard) and NOTAMs (issued by the FAA) at FDM as the Navy has done in the past, which will enable mariners to better plan trips to islands north of FDM, including the Islands Unit. See Section 3.12.3.1.1.2 (Commercial and Recreational Fishing) in the 2015 MITT Final EIS/OEIS.
- **Increased time and cost to transit around FDM because of the expanded restricted area around FDM –** Transiting between Guam, Saipan, Tinian, and Rota to islands located north of FDM (e.g., the Islands Unit) would potentially be impacted by designating a 12 NM danger zone around the FDM and limiting access to the area when the range is in use. A study conducted by the Pacific Islands Fisheries Science Center on fishing activity in the Islands Unit of the Marianas Trench Marine National Monument reported that vessels have historically traveled from the southern Mariana Islands to the Islands Unit (defined as the islands of Uracas, Maug, and Asuncion) an average of 3.8 times per year over the 30-year period from the years 1979 through 2009 (Kotowicz & Richmond, 2013). Travel to other islands north of FDM (e.g., Anatahan and Pagan) may be more frequent; however, the study did not address islands located south of the Islands Unit. Considering that trips between the populated island south of FDM and the Islands Unit would be relatively infrequent, the probability of military activities that temporarily limit

access to ocean areas within 12 NM of FDM interfering with trips to the Islands Unit would be low. The most direct route between Saipan (the northernmost populated island) and Anatahan (the closest island north of FDM) passes more than 12 NM west of FDM. Furthermore, the military will continue to announce when FDM is not in use in addition to notifying mariners of planned activities via NOTMARs and NOTAMs at FDM as the Navy has done in the past, which will enable mariners to better plan trips to islands north of FDM, including the Islands Unit. See Section 3.12.3.1.1.2 (Commercial and Recreational Fishing) in the 2015 MITT Final EIS/OEIS.

- **Request for direct compensation or development of fishery infrastructure as mitigation for loss of access to fishing grounds –** As presented in Section 3.12 (Socioeconomic Resources) of the MITT Final EIS/OEIS, the military has been conducting training and testing activities within the Study Area for decades, and has taken and will continue to take measures to prevent interruption of commercial and recreational fishing activities. The Navy limits fishing activities in only a small portion of the Study Area and only to the extent necessary to accommodate the training and testing activities. The military does not limit fishing activities from occurring in areas of the Study Area that are not being used for training and testing activities. To mitigate impacts to fishers and minimize potential interactions between military and civilian activities, the Navy will continue to publish scheduled training event times and locations on publicly accessible Navy websites and through U.S. Coast Guard issued Notices to Mariners, up to 6 months in advance of planned events. Press releases have been continuously provided to Guam and CNMI Mayors' offices and interested fishing organizations and fishers. When feasible, the military will use these same means of communication to notify the public of changes to previously published restrictions. Advanced planning on behalf of the military and effective communication of the military's plans attempt to maximize accessibility to desirable fishing locations and minimize the effect on commercial and recreational fishing activities. To the extent practicable, the Navy will continue to limit training and testing activities in and around the location of fish aggravating devices. The Navy will continue to consult with the public and local fishers on issues affecting commercial and recreational fishing in order to limit potential impacts associated with military activities. The issue of compensation to impacted fisheries is beyond the scope of the Navy's analysis in this SEIS/OEIS.
- **Displacement of fishermen from traditional fishing grounds –** Access to certain areas of the Study Area is restricted during potentially hazardous training and testing activities to ensure the safety of the public and military personnel. Most areas (with the notable exception of the 3 NM danger zone around FDM) are only restricted on a temporary basis and are accessible to the public when not in use by the military. See Section 3.12.1.4 (Environmental Justice) and Section 3.12.2.1 (Accessibility [to the Ocean and Airspace]) of this SEIS/OEIS. See also Section 3.12.3.1 (Accessibility [to the Ocean and Airspace]) and Section 3.12.3.1.1.3 (Subsistence Use) in the 2015 MITT Final EIS/OEIS.
- **Impacts on traditional fishing practices –** Traditional fishers, including subsistence fishers, typically fish from the shore or from small vessels within 3 NM of shore. The majority of training and testing activities occur in offshore waters (beyond 3 NM and in many cases beyond 12 NM) where traditional fishing typically does not occur, reducing any potential overlap with military activities. The Navy understands that individual fishers may be temporarily impacted by a particular event. The Navy will continue to communicate with the public through multiple means to alert traditional fishers of upcoming activities that may limit access to popular fishing

sites. Monitoring NOTMARs and other announcements for scheduled training and testing activities should avoid any conflicts and reduce socioeconomic impacts on traditional fishers. See Section 3.12.1.4 (Environmental Justice) and Section 3.12.2.1 (Accessibility [to the Ocean and Airspace]). See also Section 3.12.3.1 (Accessibility [to the Ocean and Airspace]), Section 3.12.3.1.1.3 (Subsistence Use), and 3.12.3.3.1.1 (Commercial and Recreational Fishing/Subsistence Use) in the 2015 MITT Final EIS/OEIS.

- **Impacts from explosives on fish stocks and traditional fishers who rely on those stocks –** The analysis in Section 3.9 (Fishes) concludes that there would be no population-level effects on any fish species, including economically important species. See Section 3.12.2.4 (Secondary Stressors) and Section 3.12.3.1.1.3 (Subsistence Use) in the 2015 MITT Final EIS/OEIS.
- **Environmental justice concerns that the people of Guam and the Northern Marianas are disproportionately impacted by military training and testing in relation to other training areas available to the U.S. Navy worldwide –** The military conducts training and testing activities very similar to activities proposed in the MITT SEIS/OEIS in Hawaii, Southern California, the Pacific Northwest, off the Atlantic coast, and in the Gulf of Mexico. The level of activity in most if not all of these locations is greater than in the MITT Study Area, and minority and low-income populations also occur in these areas.

3.13 Public Health and Safety

3.13.1 Affected Environment

The purpose of this section is to supplement the analysis of impacts on public health and safety presented in the 2015 Mariana Islands Training and Testing (MITT) Final Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS) with new information relevant to proposed changes in training and testing activities conducted at sea and on Farallon de Medinilla (FDM). Information presented in the 2015 MITT Final EIS/OEIS that remains valid is noted as such, and referenced in the appropriate sections. Any new or updated information describing the affected environment and analysis of impacts on public health and safety associated with the Proposed Action is provided in this section. Comments received from the public during scoping related to public health and safety are addressed in Section 3.13.3 (Public Comments). Comments received from the public during the Draft Supplemental EIS (SEIS)/OEIS commenting period related to public health and safety are addressed in Appendix K (Public Comment Responses).

3.13.1.1 Existing Conditions

3.13.1.1.1 Sea Space

Sea space accessibility within the MITT Study Area is the same as what is described in the 2015 MITT Final EIS/OEIS (Section 2.1.1.2, Sea and Undersea Space and Section 3.13.2.1.1, Sea Space). Only select areas have activity restrictions or prohibitions in accordance with Title 33 Code of Federal Regulations Part 334 (Danger Zone and Restricted Area Regulations). These restrictions can be permanent or temporary. The National Oceanic and Atmospheric Association (NOAA) issues nautical charts that delineate these areas. The military conducts training and testing activities in operating areas away from commercially used waterways and inside special use airspace. Scheduled training and testing activities are published by the United States (U.S.) Coast Guard in Notices to Mariners (NOTMARs) to notify the public of upcoming and potentially hazardous activities. NOTMARs are available online,[1] and email notifications can be received by registering online. Data on the number of NOTMARs issued from 2010 through 2015 for FDM and W-517 is presented in Section 3.12 (Socioeconomic Resources and Environmental Justice). As with other activities, the Navy posts NOTMARs at least 72 hours in advance of potentially hazardous training and testing activities at FDM. NOTMARs may extend restrictions out to 12 nautical miles as needed for certain training and testing activities to ensure the safety and protection of the public and the military.

Other communication outlets available to the public include the Joint Region Marianas (JRM) Public Affairs Office, which posts press releases on the JRM website and on the JRM Facebook page.[2] Interested members of the public can also follow the JRM on Twitter. Posts to the JRM Facebook page activate a Twitter post. Naval Base Guam Public Affairs posts press releases on the Naval Base Guam Facebook page,[3] and Naval Facilities Engineering Command, Marianas Public Affairs posts press releases on their Facebook page.[4]

[3] https://www.facebook.com/USNavalBaseGuam/
[4] https://www.facebook.com/navfacmarianas/

Non-military activities are not permitted on or near FDM, and aircraft and marine vessels are restricted from entering within 3 nautical miles of FDM. Even when live fire or other potentially hazardous activities are not occurring at FDM, the threat of unexploded ordnance is always present. The military prevents civilians from entering FDM when the range is scheduled for use by using visual observers on vessels that scan for non-participants in accordance with standard operating procedures. More details on these procedures are available in Section 5.7.3 (Farallon de Medinilla Access Restrictions) of the 2015 MITT Final EIS/OEIS.

Marine protected areas (MPAs) are marine areas that restrict certain human activities for conservation purposes. The 2015 MITT Final EIS/OEIS describes five MPAs (Section 3.13.2.1.1, Sea Space); however, Table 3.13-1 lists other MPAs that are located within the Study Area along with their primary conservation focus and fishing restrictions. Although fishing restrictions would decrease boat traffic within the MPAs, they could force fishermen to travel further offshore, which is more dangerous and also has the potential to overlap with other training and testing activities.

Table 3.13-1: Marine Protected Areas Within the Study Area

Marine Protected Area	Primary Conservation Focus	Fishing Restriction	Location
War in the Pacific National Historic Park	Cultural Heritage	Commercial and Recreational	Guam
Tokai Maru	Cultural Heritage	Commercial	Guam
Cormoran	Cultural Heritage	Commercial	Guam
Aratama Maru	Cultural Heritage	Commercial	Guam
Orote Ecological Reserve Area	Natural Heritage	N/A	Guam
Guam National Wildlife Refuge	Natural Heritage	Commercial and Recreational	Guam
Haputo Ecological Reserve Area	Natural Heritage	N/A	Guam
Managaha Marine Conservation Area	Cultural Heritage	Commercial and Recreational	Northern Mariana Islands
Sasanhaya Fish Reserve	Natural Heritage	Commercial and Recreational	Northern Mariana Islands
Lighthouse Reef Trochus Reserve	Natural Heritage	Commercial	Northern Mariana Islands
Laulau Bay Sea Cucumber Reserve	Natural Heritage	Commercial and Recreational	Northern Mariana Islands
Bird Island Marine Sanctuary	Natural Heritage	Commercial and Recreational	Northern Mariana Islands
Bird Island Sea Cucumber Reserve	Natural Heritage	Commercial and Recreational	Northern Mariana Islands
Forbidden Island Marine Sanctuary	Natural Heritage	Commercial and Recreational	Northern Mariana Islands

Table 3.13-1: Marine Protected Areas Within the Study Area (continued)

Marine Protected Area	Primary Conservation Focus	Fishing Restriction	Location

3.13.1.2 Airspace

General information on airspace within the Study Area can be found in the 2015 MITT Final EIS/OEIS (Section 3.13.2.1.2, Airspace); however, there have been changes to special use airspace within the Study Area in order to enhance safety. Changes include the addition of one new restricted area and new warning areas (U.S. Department of the Navy, 2015). These changes further separate non-military and military aviation activities, thereby enhancing safety. This SEIS/OEIS does not propose changes to the airspace. The military also requests that the Federal Aviation Administration issue Notices to Airmen to warn the public of upcoming military activities requiring the exclusive use of airspace. Military activity areas and special use airspace are identified on nautical and aeronautical charts to inform surface vessels and aircraft that military activities occur in the area. When necessary, airspace used by the military is restricted for short periods of time (typically on the order of hours) to cover the timeframes of training and testing activities. The Navy posts Notices to Airmen when restrictions are in place prior to initiating a training and testing activity, and the military follows standard operating procedures to visually scan an area to ensure that non-participants (i.e., civilian vessels and aircraft) are not present. More details on these procedures are available in Section 2.3.3 (Standard Operating Procedures) of this SEIS/OEIS. If non-participants are present, the military delays, moves, or cancels its activity. Public accessibility is no longer restricted once the activity concludes.

3.13.1.3 Safety and Inspection Procedures

As stated in the 2015 MITT Final EIS/OEIS (Section 3.13.2.2, Safety and Inspection Procedures), the Navy adheres to policies that ensure the safety and health of military personnel and the public. This is accomplished by utilizing communication and notification channels provided by the U.S. Coast Guard and Federal Aviation Administration as described above, considering the location when planning activities, and ensuring that training and testing activity areas are clear of non-participants before commencing.

As discussed in the 2015 MITT Final EIS/OEIS (Section 3.13.2.2, Safety and Inspection Procedures), some training and testing activities use ordnance, and the type of ordnance used would be the same as identified in the 2015 MITT Final EIS/OEIS. As such, the procedures for handling and storing of ordnance remain applicable and valid.

3.13.1.3.1 Aviation Safety

Navy procedures and policies detailing aviation safety are outlined in the 2015 MITT Final EIS/OEIS (Section 3.13.2.2.1, Aviation Safety). These policies include the Chief of Naval Operations Instruction

3770.2L and Department of Defense Instruction 4540.01, which specify procedures for planning and managing special use airspace, for conducting aircraft maneuvers, and for firing missiles and projectiles over the high seas. Additional measures involve aircrews being responsible for maintaining a lookout for non-participating aircraft while operating in warning areas and other special use airspace, as well as the implementation of the Bird/Animal Aircraft Strike Hazard program, which is discussed in detail in the 2015 MITT Final EIS/OEIS (Section 3.13.2.2.1, Aviation Safety). These procedures and policies remain applicable and valid.

3.13.1.3.2 Submarine Navigation Safety

Methods for preserving submarine navigation safety are discussed in the 2015 MITT Final EIS/OEIS (Section 3.13.2.2.2, Submarine Navigation Safety). These methods include avoiding collisions while surfaced by using visual scans, radar scans, acoustic depth finders, and satellite navigational systems, as well as avoiding areas with surface vessels while submerged by using inertial navigational charts. These methods remain applicable and valid in this SEIS/OEIS.

3.13.1.3.3 Surface Vessel Navigational Safety

The Navy's methods for ensuring navigational safety for surface vessels are discussed in the 2015 MITT Final EIS/OEIS (Section 3.13.2.2.3, Surface Vessel Navigational Safety) and can involve practicing the fundamentals of safe navigation, posting lookouts to scan for navigational hazards, or utilizing support boats to determine that all safety criteria are met. These safety methods remain applicable and valid.

3.13.1.3.4 Sound Navigation and Sounding (Sonar) Safety

Surface vessel and submarine sonar use is described in the 2015 MITT Final EIS/OEIS (Section 3.13.2.2.4, Sound Navigation and Sounding [Sonar] Safety). The Navy adheres to Naval Sea Systems Command Instruction 3150.2, Appendix 1A, which provides guidance for protecting divers during active sonar use. Guidance for protecting divers remains applicable and valid.

3.13.1.3.5 Electromagnetic Energy Safety

The electromagnetic spectrum and the applications of electromagnetic radiation are described in the 2015 MITT Final EIS/OEIS (Section 3.13.2.2.5, Electromagnetic Energy Safety). Military aircraft, ships, and submarines follow standard operating procedures, which prevent people, ordnance, or fuels from receiving levels of electromagnetic energy that exceed hazardous thresholds. The standard operating procedures that are described in Section 2.3.3 (Standard Operating Procedures) of this SEIS/OEIS remain applicable and valid.

3.13.1.3.6 Laser Safety

Lasers produce a coherent beam of light energy. The Navy uses lasers for precision range finding, as target designation/illumination devices for engagement with laser-guided weapons, for mine detection, for mine countermeasures, and for non-lethal deterrent. Testing activities include high-energy laser weapons tests to evaluate the specifications, integration, and performance of a vessel- or aircraft-mounted high-energy laser. Information regarding low-energy lasers can be viewed in the 2015 MITT Final EIS/OEIS (Section 3.13.2.2.6, Laser Safety). High-energy lasers were not analyzed in the 2015 MITT Final EIS/OEIS. The high-energy laser would be used as a weapon to disable small surface vessels. The Office of the Chief of Naval Operations Instruction 5100.27B/Marine Corps Order 5104.1C, *Navy Laser Hazards Control Program*, prescribes Navy and Marine Corps policy and guidance in the identification and control of laser hazards. The Navy observes strict precautions and has written instructions in place for laser users to ensure that non-participants are not exposed to intense light

energy. Laser safety procedures for aircraft require an initial pass over the target before laser activation to ensure that target areas are clear. During actual laser use, aircraft run-in headings are also restricted to avoid or reduce unintentional contact with personnel or non-participants. Personnel participating in laser activities are required to complete a laser safety course (U.S. Department of the Navy, 2008).

3.13.1.3.7 High-Explosive Ordnance Detonation Safety

Safety measures for high explosive detonations, particularly underwater explosions, are discussed in the 2015 MITT Final EIS/OEIS (Section 3.13.2.2.7, High-Explosive Ordnance Detonation Safety) and remain valid. General underwater detonation procedures involve ensuring impact areas are clear before commencing hazardous activities, coordinating with submarine operational authorities, and firing in accordance with current safety instructions.

3.13.1.3.8 Weapons Firing and Ordnance Expenditure Safety

The safety and inspection procedures discussed in the 2015 MITT Final EIS/OEIS remain applicable and valid to this analysis. Safety continues to be a primary concern for all training and testing activities, and all hazard areas must be clear of all non-participants prior to any use of ordnance. Training and testing activities are delayed, moved, or cancelled if there is any question about public safety.

3.13.2 Environmental Consequences

The 2015 MITT Final EIS/OEIS (Section 3.13.3, Environmental Consequences) analyzed training and testing activities currently occurring in the Study Area and considered all potential stressors related to public health and safety. Stressors applicable to public health and safety in the Study Area are the same stressors analyzed in the 2015 MITT Final EIS/OEIS with the exception of explosive stressors. In the 2015 MITT Final EIS/OEIS, explosives were addressed under acoustic stressors; however, for purposes of this analysis, explosives are analyzed as a separate stressor. The following stressors were analyzed for public health and safety. Following each stressor is a list of substressors that have been updated from the 2015 MITT Final EIS/OEIS (Section 3.13.3, Environmental Consequences):

- Underwater Energy (sonar and in-water explosives)
- In-Air Energy (radar, in-air explosives, and lasers)
- Physical Interactions (aircraft, vessels, in-water devices/targets, munitions, seafloor devices)
- Secondary Stressors (impacts on water quality from explosives [in-air explosives and in-water explosives] and explosion byproducts, metals, chemicals other than explosives, and other materials)

This section evaluates how and to what degree potential impacts on public health and safety from stressors described in Section 3.0 (Introduction) may have changed since the analysis presented in the 2015 MITT Final EIS/OEIS was completed. Tables 2.5-1 and 2.5-2 in Chapter 2 (Description of Proposed Action and Alternatives) list the proposed training and testing activities and include the number of times each activity would be conducted annually and the locations within the Study Area where the activity would typically occur under each alternative. The tables also present the same information for activities described in the 2015 MITT Final EIS/OEIS so that the proposed levels of training and testing activities under this SEIS/OEIS can be easily compared. The Navy conducted a review of federal and state regulations and standards relevant to public health and safety and reviewed literature published since 2015 for new information that could supplement the analysis presented in the 2015 MITT Final EIS/OEIS.

The analysis presented in this section also considers standard operating procedures which are discussed in Section 2.3.3 (Standard Operating Procedures) of this SEIS/OEIS. The Navy would implement these measures to avoid or reduce potential impacts on public health and safety from stressors associated with the proposed training and testing activities.

3.13.2.1 Underwater Energy

Sources of underwater energy are the same as those discussed in the 2015 MITT Final EIS/OEIS (Section 3.13.3.1, Underwater Energy) and include active sonar, underwater explosions, air guns, vessel movements, aircraft overflights, mine warfare devices, and unmanned underwater vehicles. Only recreational swimmers and scuba divers who are underwater and within an unsafe distance of training and testing activities would potentially be exposed to the underwater energy produced by these stressors.

The effect of active sonar on humans varies with the sonar frequency. Generally, mid- to low-frequencies have the greatest effect since they fall within the range of human hearing (20 hertz to 20 kilohertz). In addition to acoustic stressors, underwater explosions produce pressure waves that can cause physical injury depending on the size, type, and depth of the explosive charge and the distance between the person and the explosive. Electromagnetic energy sources and their potential impacts on public health and safety are discussed in the 2015 MITT Final EIS/OEIS (Section 3.13.3.1, Underwater Energy) and remain applicable in this discussion. In addition, standard safety buffers that are specified in Department of Defense Instruction 6055.11, *Protecting Personnel from Electromagnetic Fields* (U.S. Department of Defense, 2009), and Military Standard 464A, *Electromagnetic Environmental Effects: Requirements for Systems* (U.S. Department of Defense, 2002), would continue to be implemented to ensure public safety.

3.13.2.1.1 Impacts from Underwater Energy Stressors Under Alternative 1

While the frequency of certain activities would increase under Alternative 1, the analysis of impacts on public health and safety from underwater energy presented in this SEIS/OEIS is not dependent on the number of activities that occur. Instead, the analysis discusses how likely an activity is expected to impact public health and safety regardless of how often it occurs. Therefore, increases shown in Tables 2.5-1 and 2.5-2 for activities proposed under Alternative 1 would have no appreciable change on the impact analysis or conclusions for underwater energy as presented in the 2015 MITT Final EIS/OEIS.

Standard operating procedures, which are described in Section 2.3.3 (Standard Operating Procedures) of this SEIS/OEIS, are in place to ensure that military activities do not overlap with non-military activities (e.g., boating, swimming, and fishing). Since the only potential receptors of underwater energy stressors are recreational swimmers and divers, training and testing activities that could affect public health and safety are often held far from popular swimming and dive areas, reducing the potential for exposure. The military's safety procedures would ensure that the potential for training and testing activities to impact public health and safety under Alternative 1 would be unlikely.

3.13.2.1.2 Impacts from Underwater Energy Stressors Under Alternative 2 (Preferred Alternative)

Similar to Alternative 1, the frequency of certain activities would increase under Alternative 2 (see Table 2.5-1 and Table 2.5-2 to see changes in frequency of specific activities). However, as explained above, this analysis is not dependent on the frequency of activities but instead on how likely an activity is to produce underwater energy that would impact public health and safety. Since the only potential receptors of underwater energy stressors are recreational swimmers and divers, training and testing activities that could affect public health and safety are often held far from popular swim and dive areas,

reducing the potential for exposure. Furthermore, the military has safety procedures to ensure that the potential for training and testing activities to impact public health and safety under Alternative 2 would be unlikely.

3.13.2.1.3 Impacts from Underwater Energy Stressors Under No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Underwater energy stressors as listed above would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer underwater energy stressors within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for underwater energy impacts on public health and safety, but would not measurably improve public health and safety.

3.13.2.2 In-Air Energy

In-air energy stressors include sources of electromagnetic energy and lasers, such as radar, navigational aids, high-energy lasers, and electronic warfare systems. Current practices for protecting military personnel and the public are described in the 2015 MITT Final EIS/OEIS (Section 3.13.3.2) and remain applicable to this analysis. In addition, procedures for laser safety are described above in Section 3.13.1.3.6 (Laser Safety) as well as in Section 2.3.3.4 (Pierside Testing Safety). Training and testing activities that involve electromagnetic energy and lasers are described in the 2015 MITT Final EIS/OEIS and now also includes high-energy laser use.

High-energy lasers are used as weapons to disable surface targets. The Navy would operate high-energy laser equipment in accordance with procedures defined in the Office of the Chief of Naval Operations Instruction 5100.23G, Navy Safety and Occupational Health Program Manual (U.S. Department of the Navy, 2011). These high-energy light sources can cause eye injuries and burns if directly hit with the laser. A comprehensive safety program exists for the use of lasers. Current Navy safety procedures protect individuals from the hazard of injuries caused by laser energy. Laser safety requirements for aircraft and vessels mandate verification that target areas are clear before commencement of an exercise. In the case of aircraft, during actual laser use, the aircraft run-in headings are restricted to preclude inadvertent lasing of areas where the public may be present.

3.13.2.2.1 Impacts from In-Air Energy Stressors Under Alternative 1

The frequency of activities that generate in-air energy would increase under Alternative 1. This increase would result in an increase in ionizing radiation, which can negatively impact public health and safety following chronic exposure and from direct contact. However, repeat exposure would be limited and the impact of each exposure would be minimized due to existing safety procedures. Therefore, increases shown in Tables 2.5-1 and 2.5-2 for activities proposed under Alternative 1 would have no appreciable change on the impact analysis or conclusions for in-air energy as presented in the 2015 MITT Final EIS/OEIS.

High-energy lasers would be used during testing activities that were not previously analyzed. It is unlikely that the public would be exposed to high-energy lasers from testing activities because the Navy would not conduct these activities in proximity to the public and they would only occur in designated

areas of the Mariana Islands Range Complex. Explosives would continue to be used at FDM, but the energy produced from these explosives would be contained within their weapon danger zones, which are restricted to the public and would not have the potential to impact public health and safety. Although there would be a general increase to the frequency of in-air energy stressors, standard operating procedures for electromagnetic energy and lasers would prevent personnel and non-participants from being exposed to these stressors. The military's safety procedures would ensure that the potential for training and testing activities to impact public health and safety under Alternative 1 would be unlikely.

3.13.2.2.2 Impacts from In-Air Energy Stressors Under Alternative 2 (Preferred Alternative)

Under Alternative 2, the number of proposed training and testing activities that would generate in-air energy would increase for high-energy lasers (see Table 3.0-10), increase for explosive munitions (only for torpedoes, missiles, large-caliber projectiles, and medium-caliber projectiles [see Table 3.0-16]), and stay the same for munitions used on FDM (see Table 3.0-20) as compared to Alternative 1. However, as explained in Alternative 1, the increase in ionizing radiation exposure that would occur from increases in training and testing activities would result in only limited exposure due to existing safety procedures. Alternative 2 would also include the introduction of high-energy lasers; however, the standard operating procedures that pertain to the use of high-energy lasers and other in-air energy sources would prevent any energy being generated from impacting public health and safety. Therefore, the implementation of Alternative 2 would have no appreciable change on the impact conclusions presented in the 2015 MITT Final EIS/OEIS.

3.13.2.2.3 Impacts from In-Air Energy Stressors Under No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. In-air energy stressors as listed above would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer in-air energy stressors within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for in-air energy impacts on public health and safety, but would not measurably improve public health and safety.

3.13.2.3 Physical Interactions

As discussed in the 2015 MITT Final EIS/OEIS (Section 3.13.3.3, Physical Interactions), military aircraft, vessels, targets, munitions, towed devices, seafloor devices, and other expended materials have the potential to directly encounter recreational, commercial, institutional, and governmental aircraft, vessels, and users such as swimmers, divers, and anglers. Methods for providing notice to non-participants of Navy training and testing activities, procedures for minimizing encounters with military expended materials, and a discussion of unexploded ordnance are all outlined in the 2015 MITT Final EIS/OEIS (Section 3.13.3.3, Physical Interactions) as well as in previous sections 3.13.1.1.1 (Sea Space), 3.13.1.2 (Airspace), and 3.13.1.3 (Safety and Inspection Procedures).

3.13.2.3.1 Impacts from Physical Interaction Stressors Under Alternative 1

Under Alternative 1, there would be a general increase in activities involving vessel movements, as shown in Table 3.0-12. Increases in the frequency of vessel movements would increase vessel traffic and the probability for a physical interaction to occur between naval vessels and non-participating vessels. However, standard operating procedures and safety and inspection procedures would be in place to reduce the potential for non-participants and personnel to be physically impacted by training and testing activities. The military's safety procedures are designed to ensure that the potential for training and testing activities to impact public health and safety under Alternative 1 would be unlikely.

3.13.2.3.2 Impacts from Physical Interaction Stressors Under Alternative 2 (Preferred Alternative)

Under Alternative 2, the number of training and testing activities involving vessel movement would increase as compared to Alternative 1. However, as described in Alternative 1, the standard operating procedures and safety inspection procedures that are in place would prevent the increase in frequency of vessel movements from impacting public health and safety. Therefore, under Alternative 2, increases shown in Tables 2.5-1 and 2.5-2 would have no appreciable change on the impact conclusions presented in the 2015 MITT Final EIS/OEIS.

3.13.2.3.3 Impacts from Physical Interaction Stressors Under No Action Alternative

Under the No Action Alternative, proposed training and testing activities would not occur. Other military activities not associated with this Proposed Action would continue to occur. Physical interaction stressors as listed above would not be introduced into the marine environment. Therefore, existing environmental conditions would either remain unchanged or would improve slightly after cessation of ongoing training and testing activities.

Discontinuing the training and testing activities would result in fewer physical interaction stressors within the marine environment where training and testing activities have historically been conducted. Therefore, discontinuing training and testing activities under the No Action Alternative would lessen the potential for physical interactions to impact public health and safety, but would not measurably improve public health and safety.

3.13.2.4 Secondary Stressors

As discussed in the 2015 MITT Final EIS/OEIS (Section 3.13.3.4, Secondary Impacts), public health and safety has the potential to be impacted if sediment or water quality were degraded. Section 3.1 (Sediments and Water Quality) considered the impacts on marine sediments and water quality of explosions and explosive byproducts, metals, chemicals other than explosives, and other materials (marine markers, flares, chaff, targets, and miscellaneous components of other materials). The analysis determined that no Guam, Commonwealth of the Northern Marianas Islands (CNMI), or federal standards or guidelines would be violated under any of the alternatives. Although a general increase in training and testing activities and military expended materials would occur, training and testing activities would not significantly degrade sediment or water quality or contaminate the food supply as discussed in Sections 3.1 (Sediments and Water Quality) and 3.9 (Fishes). In addition, because standards and guidelines are structured to protect human health, and no violations would occur, no secondary impacts on public health and safety would result from training and testing activities. Sections 3.9 (Fishes) and 3.12 (Socioeconomic Resources and Environmental Justice) discuss the impacts that the Proposed Action would have on fish and fisheries in the Study Area.

3.13.3 Public Comments

The public raised a number of issues during the scoping period in regard to public health and safety. The issues are summarized in the list below. Comments received from the public during the Draft SEIS/OEIS commenting period related to public health and safety are addressed in Appendix K (Public Comment Responses).

- **Impacts of sonar testing on human swimmers and divers –** Swimmers and recreational divers are not expected to be near training and testing activity locations where active sonar activities would occur because of the strict procedures for clearance of nonparticipants before conducting activities. As discussed in the 2015 MITT Final EIS/OEIS (Section 3.13.3.1, Underwater Energy), the potential for the public to be exposed to these stressors would be limited to divers within unsafe proximity of an event. SCUBA diving is a popular recreational activity that is typically concentrated around known dive attractions such as reefs and shipwrecks. In general, recreational divers should dive at depths not exceeding 130 feet (40 meters) (Professional Association of Diving Instructors, 2011). This depth limit typically limits this activity's distance from shore. Therefore, training and testing activities closest to shore have the greatest potential to co-occur with the public. In addition, swimmers and recreational SCUBA divers are not expected to be near Navy pierside locations because access to these areas is controlled for safety and security reasons. Locations of popular offshore diving spots are well documented, dive boats are typically well marked, and diver-down flags would be visible from the Navy ships conducting training and testing activities. Therefore, co-occurrence of recreational divers and Navy activities is unlikely.
- **Potential risks from unexploded ordnance –** As discussed in the 2015 MITT Final EIS/OEIS (Section 3.13.3.3, Physical Interactions), munitions have low failure rates and generally function as intended. While fishing activities may encounter undetonated ordnance lying on the ocean floor, such an encounter would be unlikely given the large size of the Study Area and because the density of munitions in the Study Area is low. The Army Corps of Engineers prescribes the following procedures if military munitions are encountered: recognize when you may have encountered a munition, retreat from the area without touching or disturbing the item, and report the item to local law enforcement by calling 911 or the U.S. Coast Guard. More information can be viewed at the following link: http://uxoinfo.com/blogcfc/client/enclosures/uxooverview.pdf.
- **Impacts on water quality from explosives, unexploded ordnance, and military expended materials –** As discussed in Section 3.1.4 (Summary of Potential Impacts [Combined Impact of All Stressors] on Sediments and Water Quality) of the 2015 MITT Final EIS/OEIS, additive impacts from explosives, explosive byproducts, metals, chemicals other than explosives, and miscellaneous other materials would be measurable but would not exceed applicable standards and guidelines, which indicate the levels where there would be an impact on human health. The impact analysis in Section 3.1 (Sediments and Water Quality) of this SEIS/OEIS addresses impacts on water quality from all sources associated with the Proposed Action and indicates that there would be no appreciable change from the environmental baseline.
- **Chemical exposure to humans from training and testing activities –** As discussed in Section 3.2.4 (Summary of Potential Impacts [Combined Impacts of All Stressors] on Air Quality) of the 2015 MITT Final EIS/OEIS, emissions associated with Study Area military operations primarily

occur offshore. Fixed-wing aircraft emissions typically occur above the 3,000 feet (914 meters) mixing layer. Even though these stressors can co-occur in time and space, atmospheric dispersion would occur so that the impacts would be short term. Changes in criteria and hazardous air pollutant emissions are not expected to be detectable, so the air quality is expected to fully recover before a subsequent activity. For these reasons, impacts on air quality from combining these resource stressors are expected to be similar to the impacts on air quality for any of these stressors taken individually with no additive, synergistic, or antagonistic interactions.

- **Training and testing activity safety measures to prevent harm to the CNMI economy –** A number of standard operating procedures, which were described in Section 2.3.3 (Standard Operating Procedures) of this SEIS/OEIS as well as the safety and inspection procedures discussed in Section 3.13.1.3 (Safety and Inspection Procedures) above are in place to ensure that military activities do not interfere or pose health risks to the public. There are no known instances of harm to the economy within the Study Area that have been reported due to safety measures associated with current training and testing activities. Standard operating procedures allow fishermen to continue to use the ocean without fear and allow tourists to come to the CNMI without reservations.
- **Fishermen safety –** As discussed above in Section 3.13.1.1.1 (Sea Space), the Navy uses Local NOTMARs, NOTMARs, and Marine Broadcast NOTMARs to advise local mariners of scheduled training and testing activities to avoid encountering fishers and boaters. In addition, the Navy also follows standard operating procedures that prevent military activities from occurring in the presence of non-participants. These standard operating procedures include ensuring impact areas and targets are unpopulated prior to potentially dangerous activities, canceling or delaying activities if public or personnel safety is a concern, and implementing temporary access restrictions to training and testing areas when appropriate to ensure public safety.
- **Spills and accidental releases of fuel or other hazardous materials –** Navy policies and procedures identified in Navy instructions, such as the *Environmental Readiness Program Manual*, include directives regarding waste management, pollution prevention, and recycling. These instructions are mandatory and minimize the likelihood of spills or accidental releases of fuel or other hazardous materials.
- **Health risks from a contaminated food supply –** The Record of Decision for the 2015 MITT Final EIS/OEIS indicated that there would be a negligible impact on water quality and that it would not affect the marine environment. Since there would be no significant change in water quality, and fish would not ingest increased amounts of contaminants as discussed in Section 3.9 (Fishes), the food supply would not be contaminated from proposed activities.

4 Cumulative Impacts

4.1 Principles of Cumulative Impacts Analysis

The approach taken herein to analyze cumulative effects meets the objectives of the National Environmental Policy Act (NEPA) of 1969, Council on Environmental Quality (CEQ) regulations, and CEQ guidance, and has not changed from the approach as described in the 2015 Mariana Islands Training and Testing (MITT) Final Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS) (Council on Environmental Quality, 1997; U.S. Department of the Navy, 2015b).

4.1.1 Determination of Significance

Per the CEQ's *Considering Cumulative Effects Under the NEPA* (Council on Environmental Quality, 1997), the "levels of acceptable change used to determine the significance of effects will vary depending on the type of resource being analyzed, the condition of the resource, and the importance of the resource as an issue." Furthermore, "this change is evaluated in terms of both the total threshold beyond which the resource degrades to unacceptable levels and the incremental contribution of the proposed action to reaching that threshold." In practice, "the analyst must determine the realistic potential for the resource to sustain itself in the future and whether the proposed action will affect this potential." In other words, for a proposed action to have a cumulatively significant impact on an environmental resource, two conditions must be met. First, the combined effects of all identified past, present, and reasonably foreseeable projects, activities, and processes on a resource, including the effects of the proposed action, must be significant. Second, the proposed action must make a measurable or meaningful contribution to that significant cumulative impact.

4.1.2 Identifying Region of Influence for Cumulative Impacts Analysis

The region of influence for analyses of cumulative impacts can vary for different resources and environmental media. CEQ guidance (Council on Environmental Quality, 1997) indicates that the region of influence for cumulative impacts almost always should be expanded beyond those for the project-specific analyses. This guidance continues, indicating that one way to evaluate the region of influence is to consider the distance an effect can travel, and it identifies potential cumulative assessment boundaries accordingly. For air quality, the potentially affected air quality regions are the appropriate boundaries for assessment of cumulative impacts from releases of pollutants into the atmosphere. For water resources and land-based effects, watershed boundaries may be the appropriate regional boundary. For wide-ranging or migratory wildlife, specifically marine mammals, fish, sea turtles, and marine birds, any impacts of the Proposed Action might combine with the impacts of other activities or processes within the range of the population.

The region of influence for evaluating the cumulative impacts of the Proposed Action are defined for each resource in Section 4.4 (Resource-Specific Cumulative Impacts). The basic geographic boundary for the majority of resources analyzed for cumulative impacts in this Supplemental EIS (SEIS)/OEIS is the entire MITT Study Area (Figure 2.1-1). The region of influence for cumulative impacts analysis for some resources are expanded to include activities outside the Study Area that might impact migratory or wide-ranging animals. Other activities potentially originating from outside the Study Area that are considered in this analysis include impacts associated with maritime traffic (e.g., vessel strikes and underwater noise) and commercial fishing (e.g., bycatch and entanglement).

Comments received from the public during scoping related to cumulative impacts are addressed in Section 4.6 (Public Comments). Comments received from the public during the Draft Supplemental EIS

(SEIS)/OEIS commenting period related to cumulative impacts are addressed in Appendix K (Public Comment Responses).

4.2 Projects and Other Activities Analyzed for Cumulative Impacts

The cumulative analysis includes consideration of past, present, and reasonably foreseeable future actions that overlap in time and space with the Proposed Action. Actions and projects that have been added to this cumulative analysis since the 2015 MITT Final EIS/OEIS include the Saipan water system improvements project, the wastewater system for Saipan, the Saipan Resort Hotel, the Plumeria Resort and Casino, aquaculture, and undersea communications cables. For past actions, the cumulative impacts analysis only considers those actions or activities that have had ongoing impacts that may be additive to impacts of the Proposed Action. Likewise, present and reasonably foreseeable future actions selected for inclusion in the analysis are those that may have effects additive to the effects of the Proposed Action as experienced by specific environmental receptors.

The cumulative impacts analysis makes use of the best available data, quantifying impacts where possible and relying on the qualitative description and best professional judgment where detailed measurement is unavailable. Because specific information and data on past projects and actions are typically scarce, the analysis of past effects is often qualitative (Council on Environmental Quality, 1997). Likewise, analysis of ongoing actions is often inconsistent or unavailable. All likely future development or use of the region is considered to the greatest extent possible, even when a foreseeable future action is not planned in sufficient detail to permit complete analysis (Council on Environmental Quality, 1997).

The cumulative impacts analysis is not bound by a specific future timeframe. The Proposed Action includes general types of activities addressed by this SEIS/OEIS that are expected to continue indefinitely, and the associated impacts could occur indefinitely. Likewise, some reasonably foreseeable future actions and other environmental considerations addressed in the cumulative impacts analysis are expected to continue indefinitely (e.g., seismic surveys, maritime traffic, commercial fishing). While Navy training and testing activities requirements change over time in response to world events, it should be recognized that available information, uncertainties, and other practical constraints limit the ability to analyze cumulative impacts for the indefinite future. Navy environmental planning and compliance for training and testing activities is an ongoing process, and the Navy anticipates preparing new or supplemental environmental planning documents covering changes in training and testing activities in the Study Area as necessary. These future environmental planning documents would include a cumulative impacts analysis based on information available at that time.

Table 4.2-1 lists the other actions and other environmental considerations identified for the cumulative impacts analysis, including activities presented in the 2015 MITT Final EIS/OEIS with updated information. Descriptions of each action and environmental consideration carried forward for analysis are provided in the sections that follow. For the perspective of general project locations, please refer to Figures 2.1-1 through 2.1-4, which depict the Study Area, boundaries of individual training and testing activities locations, and large marine ecosystems and open ocean areas within and adjacent to the Study Area.

Military Mission, Testing, and Training Activities						
Commonwealth of the Northern Mariana Islands (CNMI) Joint Military Training (CJMT)	CNMI	The Draft 2015 Commonwealth of the Northern Mariana Islands (CNMI) Joint Military Training (CJMT) EIS/OEIS (U.S. Department of the Navy, 2015a) provided a draft evaluation of the potential impacts associated with alternatives for meeting U.S. Indo-Pacific Command Service Components' unfilled unit-level and combined-level training requirements in the Western Pacific. The draft action alternatives proposed the establishment of a series of live-fire and maneuver ranges and training areas; expansion of existing ranges and training areas; and construction of new ranges and training areas within the CNMI, including amphibious operations. The Notice of Intent to complete the EIS/OEIS was published in the *Federal Register* on March 14, 2013. Following an in-depth review of public comments on the proposed construction of military training areas in CNMI, and consultation with CNMI Executive Branch, the Department of Defense (DoD) announced in October 2015 it would issue a Revised Draft EIS for its proposed actions for the CJMT. The proposed revised Draft EIS will evaluate contribution to the cumulative effects of ongoing actions in the CNMI. Specifically, the resources evaluated and the information collected as part of the CJMT project to date will contribute to cumulative impacts, including geology and soils, water resources, air quality, noise, airspace, land and submerged land use, recreation, terrestrial biology, marine biology, cultural resources, visual resources, transportation, utilities, socioeconomics and environmental justice, hazardous materials and waste, and public health and safety.	Resource management measures include avoidance and minimization measures, best management practices, and standard operating procedures.			C/O

CNMI Joint Region Marianas Integrated Natural Resources Management Plan (INRMP)	CNMI	In June 2019, the Navy completed the Joint Region Marianas Integrated Natural Resources Management Plan (INRMP). An INRMP is a long-term planning document designed to guide the management of natural resources on military-administered areas, support military missions, and ensure compliance with environmental laws and regulations. The purpose of the 2019 Joint Region Marianas INRMP is to maintain long-term ecosystem health and operational requirements of the DoD's mission while minimizing impacts on natural resources. It is also the intent of the INRMP to provide a conservation benefit to federally protected species (ESA-listed corals, fishes, sea turtles, and marine mammals). In order to meet these purposes, the Joint Region Marianas INRMP establishes a list of management projects for ESA-listed corals, fishes, sea turtles, and marine mammals that either improve the understanding of these species in the wild or are designed to protect species and their habitat without infringing on the DoD's military mission. An INRMP also supports an installation's mission while conserving and rehabilitating installation resources for multiple use, sustainable yield, and biological integrity. National Marine Fisheries Service (NMFS), as a partner in the development of the Joint Region INRMP, endorsed the Joint Region Marianas INRMP in June 2019. Specific management goals subject to annual funding availability under the June 2019 INRMP include • Coral Habitat Enhancement (surveys, management) [*Naval Base Guam, Andersen Air Force Base, Tinian Military Lease Area*] • Marine Flora Management (survey subtidal areas for algae and seagrasses) [*Naval Base Guam, Tinian Military Lease Area*] • Marine Resources Data Management (Coordination with Pacific Islands Fisheries Science Center for surveys) [*Naval Base Guam,*	Implementation of the Joint Region Marianas INRMP program and the focused strategies and actions of the management projects for marine resources provides a conservation benefit to the marine ecosystem in the nearshore waters of military-owned or leased lands by maintaining and enhancing marine community structure, function, species diversity, and resiliency. Using this regional ecosystem-based approach for managing protected species and their associated ecosystems ensures that the Navy remains in compliance with federal and territorial laws while supporting the	X	X	X

				Past	Present	Future
Divert Activities and Exercises	Saipan and Tinian	The USAF proposed improvements to an existing airfield near the Philippine Sea in support of expanding mission requirements in the western Pacific, along with divert capabilities for current, emerging, and future training activities. A Draft EIS analyzing environmental impacts associated with the divert activities and exercises was published in June 2012 and found adverse effects could occur from the construction phase of the project on cultural resources, as well as adverse impacts to socioeconomic resources and environmental justice, and human health and safety. The USAF published a Revised Draft Divert EIS in 2015 and released a Final EIS and Record of Decision in 2016 (U.S. Department of the Air Force, 2016). The USAF selected the preferred alternative, Alternative 2 - Modified Tinian Alternative and specifically the North Option as the location to implement the proposed action described in the Divert EIS. In spring 2018 the U.S. Air Force published the intention to prepare a Supplemental EIS to assess the potential environmental consequences associated with proposed Tinian Divert Infrastructure Improvements. On May 17, 2019, the USAF published the NOA for the Draft SEIS for the proposed Tinian Divert Infrastructure Improvements. The NOA began the public review period for the Draft SEIS, which ended on July 1, 2019. Substantive comments received during the public review period will be considered during preparation of the Final SEIS. The USAF now proposes to construct a fuel pipeline, and associated infrastructure at the seaport, to transport fuel from the seaport to the airport. Therefore, the USAF also proposes to improve certain existing roads between the seaport and airport that would be used to support Divert-related projects. Additional information about the proposed action is provided on the project website. Therefore, this project may contribute to the cumulative impacts on natural, noise, cultural and socioeconomic resources in the Study Area.	Mitigation measures will be implemented to minimize, avoid, rectify, reduce, or compensate for potential impacts on specific resource areas. There are mitigation measures for noise during construction, air quality, airspace and airfield environment, geology and soils, water resources, terrestrial biological resources, cultural resources, land use, hazardous materials and wastes, infrastructure and utilities, socioeconomic resources and environmental justice, and human health and safety. Foreign Navies Training and Testing Activities	Study Area	As the navies of the world increase their "blue water" capabilities, the presence of foreign military within the Study Area will also likely increase. Foreign military vessels currently transit through the Global Commons and international waters within the Study Area while en route to and from Guam, Hawaii, and other locations in and bordering the Pacific. As the extent of naval activities conducted by sovereign vessels and embarked aircraft while in the MITT is not quantified nor quantifiable, it is very likely that routine systems checks as well as opportunistic training and testing occurs. The resources impacted by ongoing and proposed MITT activities would also be exposed to similar stressors (e.g., acoustics from sonar and explosives, vessel strike) introduced by foreign vessels and aircraft conducting activities not related to the MITT Proposed Action.		O	O	O
Guam and Commonwealth of the Northern Mariana Islands (CNMI) Military Relocation EIS/Guam CNMI Military Relocation (2012 Roadmap Adjustments) SEIS	Guam	In July 2015, the Final SEIS Guam and Commonwealth of the Northern Mariana Islands Military Relocation (2012 Roadmap Adjustments) was completed (U.S. Department of the Navy, 2015b). The Final SEIS analyzed the potential environmental impacts of five action alternatives for the family housing component of the proposed action and five action alternatives for the live-fire training range complex component, plus a no action alternative. The proposed action was to construct and operate a cantonment area, family housing, and a Live-Fire Training Range Complex on Guam to support the Marine Corps relocation. The Navy selected the preferred alternative as described in the Final 2015 SEIS. The preferred alternative included cantonment and family housing Alternative E with the U.S. Marine Corps cantonment to be located at Navy Computer and Telecommunications Station – Guam (Finegayan), and family housing to be located at Andersen Air Force Base. The Live-Fire Training Range Complex option selected was Alternative 5, to be located at Andersen Air Force Base – Northwest Field. The Live-Fire Training Range Complex also includes a stand-alone hand	Mitigation measures will be implemented to minimize, avoid, rectify, reduce, or compensate for potential impacts on specific resource areas. There are mitigation measures for water resources, terrestrial biological resources, marine biological resources, cultural resources, utilities, socioeconomic resources, and environmental justice	C	C	O

				Past	Present	Future
		grenade range at Andersen South. The Record of Decision for the SEIS includes cantonment and family housing at the Navy Computer and Telecommunications Station in the Finegayan area of Guam, and family housing to be located at Andersen AFB. The Live Fire Training Range Complex would be located at Andersen AFB, Northwest Field and includes a stand-alone hand grenade range at Andersen South (U.S. Department of the Air Force, 2016). Potential impacts were analyzed for geological and soil resources, water resources, air quality, noise, airspace, land and submerged land use, recreational resources, terrestrial biological resources, marine biological resources, cultural resources, visual resources, ground transportation, marine transportation, utilities, socioeconomic resources and general services, hazardous materials and waste, public health and safety, and environmental justice. Continuing cumulative impacts could occur for water resources, air quality, noise, airspace, recreational resources, terrestrial biological resources, ground transportation, utilities, and socioeconomic resources and general services.	and the protection of children.			
Surveillance Towed Array Sensor System Low Frequency Active Sonar	Pacific Ocean, Atlantic Ocean, Indian Ocean, and the Mediterranean Sea	The Navy utilizes Surveillance Towed Array Sensor System Low Frequency Active Sonar systems onboard several T-AGOS class vessels in the western and central North Pacific Ocean, not including polar waters, and the southwestern Indian Ocean. The Navy is currently conducting covered SURTASS LFA sonar activities under a Letter of Authorization (LOA) published in the Federal Register on August 12, 2019, effective through August 11, 2026. The Navy has updated its relevant environmental planning and compliance documents and published the Final SEIS/OEIS for Surveillance Towed Array Sensor System Low Frequency (SURTASS LFA) Sonar in June 2019 (U.S. Department of the Navy, 2019). National Marine Fisheries Service (NMFS) published a Proposed Rule on the project in March 2019 in the	The objective of mitigation for the employment of Surveillance Towed Array Sensor System Low Frequency Active Sonar is to reduce or avoid potential exposures of marine mammals, sea turtles, and human divers to	O	O	O

		Federal Register, and NMFS issued an ESA Programmatic Biological Opinion/Incidental Take Statement for SURTASS LFA Sonar (effective with 2019 MMPA 7-Year Final Rule from 2019 to 2026) in July 2019 (United States Navy and Permits and Conservation Division et al., 2019). The underwater sound produced by this activity may contribute to the cumulative impacts on marine mammals and sea turtles in the Study Area (U.S. Department of the Navy, 2012), as the SURTASS LFA Study Area overlaps the entire MITT Study Area. The underwater sound produced by this project may contribute to the cumulative impacts on marine mammals and sea turtles in the Study Area.	Surveillance Towed Array Sensor System Low Frequency Active Sonar transmissions.			
Terminal High-Altitude Area Defense (THAAD) Permanent Stationing in Guam	Andersen Air Force Base, Guam	The Environmental Assessment (EA) for this project documents the environmental impacts associated with the expeditionary (temporary) placement and operation of a THAAD ballistic missile defense battery at Andersen Air Force Base in Guam, and from the proposed permanent stationing of the THAAD battery at its current location on Northwest Field (NWF). As a secondary, connected action to the expeditionary deployment and proposed permanent stationing of the THAAD battery in Guam, this EA also analyzes the potential impacts from the expansion of the NWF cargo drop zone training area that was encumbered by THAAD operations (U.S. Army, 2015). Other Commercial Industries						
Aquaculture	Oceans worldwide (including the Guam Aquaculture and Development Training Center in Mangilao [Fadian Hatchery])	Aquaculture is the farming of aquatic organisms such as fish, shellfish, and plants. Globally, 29 percent of stocks are fished at biologically unsustainable levels, and aquaculture helps meet demand and offsets stress to wild populations (National Marine Fisheries Service, 2015b). Aquaculture production reached an all-time high of 97 million metric tons in 2013 and is the fastest-growing form of food production, at 6 percent per year globally. Forty-seven percent of aquaculture operations occur in the Pacific Ocean. On Guam, the largest and oldest aquaculture center in the Western Pacific, the Fadian Hatchery, has been operating since the 1970s. A recent bill would expand aquaculture in Guam and improve the facilities at the Fadian Hatchery. The threats of aquaculture operations on wild fish populations include reduced water quality, competition for food, predation by escaped or released farmed fishes, the spread of disease and parasites, and reduced genetic diversity (Kappel, 2005). These threats become apparent when farmed fish escape and enter the natural ecosystem (Hansen & Windsor, 2006; Ormerod, 2003). The Marine Aquaculture Policy provides direction to enable the development of sustainable marine aquaculture (National Marine Fisheries Service, 2015b).		C/O	C/O	C/O

				Past	Present	Future
Coastal Land Development and Tourism	Coastline	Coastal development intensifies use of coastal resources, resulting in potential impacts on water quality, marine habitat, and air quality. Coastal land development in the Study Area is both intensive and extensive. Development continues to impact coastal resources through point and non-point source pollution, concentrated recreational use, intensive ship traffic using major port facilities, and coastal tourism (e.g., hotels, resorts, restaurants, food industry, vacation homes, second homes) and supporting infrastructure (e.g., retail businesses, marinas, fishing tackle stores, dive shops, fishing piers, recreational boating harbors, beaches, recreational fishing facilities). Coastal development is regulated by states and territories through the Coastal Zone Management Act and associated state and local programs. Chapter 6 (Additional Regulatory Considerations) provides additional information on coastal zone management in the Study Area. Coastal development intensifies use of coastal resources through dune and nearshore habitat loss and disturbance, point and non-point source water pollution, entrainment in outflows and other structures, and air quality degradation. Self-contained underwater breathing apparatus (SCUBA) and snorkeling have the potential to degrade reef systems through disturbance and collecting. Collisions between whale-watching ships and whales are common. Temporary permits could be obtained from the CNMI Homeland Security and Emergency Management Office for various ecotourism activities. It is anticipated these activities would occur in the future (U.S. Department of the Navy, 2015a). Commercial Fishing	Pacific Ocean	Commercial fishing constitutes an important and widespread use of the ocean resources throughout the Study Area, and can adversely affect marine species and habitats. Potential impacts include overfishing of targeted species and bycatch, both of which negatively affect fish stocks and other marine resources. Bycatch is the capture of fish, marine mammals, sea turtles, marine birds, and other non-targeted species that occurs incidental to normal fishing operations. Use of mobile fishing gear, such as bottom trawls, disturbs the seafloor and reduces structural complexity. Indirect impacts of trawls include increased turbidity, alteration of surface sediment, removal of prey (leading to declines in predator abundance), removal of predators, ghost fishing (i.e., lost fishing gear continuing to ensnare fish and other marine animals), and generation of marine debris. Lost gill nets, purse seines, and long lines may foul and disrupt bottom habitats and have the potential to entangle or be ingested by marine mammals. Jackson et al. (2001) analyzed paleoecological records of marine sediments from 125,000 years ago to present, archaeological records from 10,000 years before the present, historical documents, and ecological records from scientific literature sources over the past century. The analysis concluded that ecological extinction caused by overfishing precedes all other pervasive human disturbance of coastal ecosystems, including pollution and anthropogenic climate change. Fisheries bycatch has been identified as a primary driver of population declines in several groups of marine species, including sharks, mammals, marine birds, and sea turtles (Wallace et al., 2010). Therefore, commercial fishing may contribute to cumulative impacts on marine mammals, sea turtles, fish, and marine habitats in the Study Area.	Various bycatch mitigation technologies, quotas, and seasonal restrictions required per the fishery-specific permit process	O	O	O
Grand Mariana Casino and Hotel Resort	Garapan	This project plans for potentially up to 2,000 hotel rooms in stages, beginning with a 250-room hotel and casino (U.S. Department of the Air Force, 2016).				C/O

Maritime Traffic	Pacific Ocean	Portions of the Study Area are heavily traveled by commercial, recreational, and government marine vessels, with several commercial ports occurring in or near the Study Area. Section 3.12 (Socioeconomic Resources) provides additional information for marine vessel traffic in the Study Area. Primary concerns for the cumulative impacts analysis include vessels striking marine mammals and sea turtles, the introduction of non-native species through ballast water, and underwater sound from ships and other vessels. Therefore, maritime traffic may contribute to the cumulative impacts on marine mammals and sea turtles in the Study Area. Additionally, air and water quality in busy ports can be diminished due to engine emissions and fuel leaks. Secondary impacts include maintenance of port infrastructure, which often includes dredging requirements to maintain channel depths, and habitat loss and degradation in coastal habitats.	Continued adherence to state and federal marine traffic and operations regulations	O	O	O
Plumeria Resort and Casino	Tinian	Construction is slated to run into 2027. The hotel would include over 6,000 accommodation units and be built in three phases to include villas, a casino, golf course, water park, shops, restaurants, and new roads over 151 hectares of property at Puntan Diablo Cove on Tinian (U.S. Department of the Air Force, 2016). The resources evaluated that could contribute to cumulative impacts include water resources, air quality, cultural resources, geology and soils, terrestrial resources, and socioeconomic resources.			C	C/O
Project ATISA	Undersea between Guam, Saipan, Rota, and Tinian	The DoCoMo Pacific and NEC Corporation built a 175-mile optical fiber cable system that connects Guam and the CNMI and offers new wireless, cable TV, home phone, and broadband services.		C	O	O

				Past	Present	Future
Recreational and Cultural Fishing	Pacific Ocean	Recreational and cultural fishing includes impacts from vessel traffic (e.g., strike, noise, water pollution, marine debris) and can compound impacts on fish stocks already experiencing exploitation. Recreational and cultural fishing and boat traffic usually occurs nearshore rather than in the deeper open ocean, and recreational/cultural traffic typically frequents popular locations, which can concentrate damage in these areas from anchors or other bottom-disturbing equipment.	Operational regulations, seasonal restrictions, licensing, and quotas used to manage and mitigate negative effects of recreational and cultural fishing, such as geographic limitations (i.e., no fishing in refuges/marine preservation areas)	O	O	O
Saipan Water System Improvements	Saipan (Multiple Sites)	The project will provide focus and direction for meeting a U.S. EPA stipulated order to meet Clean Water Act and the Safe Drinking Water Act requirements in Saipan on existing water quality outputs. Construction of the project began in 2012 and is expected to occur through 2020 (U.S. Department of the Air Force, 2016). The resources evaluated that could contribute to cumulative impacts include public health and safety, socioeconomic resources, and water quality.		C	C	C/O
Wastewater System for Saipan	Saipan (Multiple Sites)	The project is updating the existing water/sewer system due to a U.S. Federal Court order. The rehabilitated water/sewer system will be compliant with U.S. Environmental Protection Agency (EPA) requirements. Construction of the project began in 2012 and is expected to occur through 2020 (U.S. Department of the Air Force, 2016). The resources evaluated that could contribute to cumulative impacts include public health and safety, socioeconomic resources, and water quality.		C	C	C/O

Seismic Surveys	Waters near the Study Area in the Territory of Guam and the Commonwealth of the Northern Mariana Islands	Seismic surveys are typically accomplished by towing a sound source, such as an airgun array that emits acoustic energy in timed intervals behind a research vessel. The transmitted acoustic energy is reflected and received by an array of hydrophones. This acoustic information is processed to provide information about geological structure below the seafloor. The oil and gas industry uses seismic surveys to search for new hydrocarbon deposits. Also, academic geologists use them to study plate tectonics and other topics. The underwater sound produced by these surveys could affect marine life, including marine mammals. For example, the potential exists to expose some animals to sound levels exceeding 180 decibels referenced to 1 micropascal root mean square, which would in turn potentially result in temporary or permanent loss of hearing (Bureau of Ocean Energy Management, 2011). All seismic surveys conducted by U.S. vessels are subject to the Marine Mammal Protection Act (MMPA) authorization process administered by NMFS, as well as the NEPA process associated with issuing MMPA authorizations.	Specific mitigations and conditions are designated for implementation during seismic surveys by the NMFS in MMPA authorizations to reduce impacts to marine mammals	O	O	O
Tinian Airport Improvements	Airport on Tinian	The project includes (1) relocation of the Aircraft Rescue and Fire Fighting Facility building, (2) terminal improvements, (3) acquisition of a 1,500-gallon Aircraft Rescue and Fire Fighting Facility vehicle, and (4) a new water line (U.S. Department of the Air Force, 2016).		C	C	O
Undersea Communications Cables	Pacific Ocean/ Connections between Guam and Hawaii and Asia	Submarine cables provide the primary means of voice, data, and Internet connectivity between the mainland U.S. and the rest of the world (Federal Communications Commission, 2017). The Federal Communications Commission grants licenses authorizing cable applicants to install, own, and operate submarine cables and associated landing stations in the United States. Cables are installed by specialized boats across flat ocean surfaces and	Continued adherence to international marine construction and operational regulations	C/O	C/O	C/O

				Past	Present	Future
		dug into the seabed in shallow areas. Over 550,000 mi. of cables currently exist in the world's oceans. SEA-US trans-Pacific cables will be routed to avoid congested earthquake prone regions and to optimize stable connectivity between the United States and Asia with landing stations in Hawaii and Guam. DoCoMo's ATISA network also is in operation and connects Guam, Saipan, Rota, and Tinian. Other telecom and consortiums continue to discuss the potential submarine cable projects in the region. Cable networks will continue to be updated in the future creating job opportunities and benefits to professions where cables connect users to the internet for less cost (Losinio, 2017). Potential impacts of installation and maintenance activities would include noise and vessel strike from boat traffic and increased seafloor disturbance and sedimentation in localized areas where the cable is installed. Likewise, electromagnetic fields are generated by some cables that may be sensed by and affect the migration behavior of some fish, sharks, rays, and eels (Bureau of Ocean Energy Management, 2016).				
Research and Conservation						
Academic Research	Global	Wide-scale academic research is conducted in the Study Area by federal entities, such as the Navy and National Oceanic and Atmospheric Administration/NMFS, as well as state and private entities and other partnerships. Although academic research aims to capture data without disturbing the ambient conditions of the ocean environment, vessels contribute to traffic, noise, and strike hazard; seismic activity contributes noise; and various other collection methods, such as trawling, could be disruptive to the ecosystems under observation. Impacts from academic research operations can be similar to the impacts expected from oil and gas airgun survey activities, when	NMFS and local government programs manage scientific research permits for certain activities	O	O	O

Pollution Prevention Grant	CNMI	The CNMI Bureau of Environmental and Coastal Quality provided this grant to support CNMI programs that reduce the environmental impact of local businesses significantly. The impacts of the programs the grant supported were to reduce pollution in air, water, and land during construction and operations by setting requirements and conditions for the Bureau of Environmental and Coastal Quality's permitting process.		O	O	O
Ocean Pollution and Ecosystem Alteration						
Noise	Global	Ambient noise is the collection of ever-present sounds of both natural and human origins. Ambient noise in the ocean is generated by sources that are natural such as physical (e.g., earthquakes, rainfall, waves breaking, and lightning hitting the ocean), biological (e.g., snapping shrimp and the vocalizations of marine mammals), and anthropogenic (human-generated) sources. Anthropogenic sources have substantially increased ocean noise since the 1960s, and include commercial shipping, oil and gas exploration and production activities (including air gun, sonar, drilling, and explosive decommissioning), commercial and recreational fishing (including vessel noise, fish-finding sonar, fathometers, and acoustic deterrent and harassment devices), military (testing, training, and mission activities), shoreline construction projects (including pile driving), recreational boating and whale-watching activities, offshore power generation (including offshore wind farms), and research (including sound from air guns, sonar, and telemetry). The contribution of military and non-military vessel traffic to the underwater noise experienced in the Study Area is discussed in Section 3.0.4.1.2 (Vessel Noise).		O	O	O

Marine Debris Section 3.1.1.1.1 (Marine Debris and Water Quality)	Global	Marine debris is any anthropogenic object intentionally or unintentionally discarded, disposed of, or abandoned that enters the marine environment (National Marine Fisheries Service, 2006). Common types of marine debris include various forms of plastic and abandoned fishing gear. Marine debris degrades marine habitat quality and poses ingestion and entanglement risks to marine life and birds (National Marine Fisheries Service, 2006). Plastic debris is a major concern because it degrades slowly and many plastics float. The floating debris is transported by currents throughout the oceans and has been discovered accumulating in oceanic gyres (Law et al., 2010). Additionally, plastic waste in the ocean chemically attracts hydrocarbon pollutants such as polychlorinated biphenyl and dichlorodiphenyltrichloroethane, which accumulate up to one million times more in plastic than in ocean water (Mato et al., 2001). Fish, marine animals, and birds can mistakenly consume these wastes that contain elevated levels of toxins, instead of their prey. In the North Pacific Subtropical Gyre, it is estimated that the fishes in this area are ingesting 12,000–24,000 U.S. tons of plastic debris a year (Davison & Asch, 2011). CNMI has attempted to reduce the occurrence of marine debris under Section 309 of the Coastal Zone Management Act as amended in 1990 and 1996, through the CNMI Department of Coastal Resources Management which implements fines and penalties for violators.		O	O	O

Table 4.2-1: Past, Present, and Reasonably Foreseeable Actions (continued)

Factor/Project	Location	Project Description	Summary of Impact Minimization and Mitigation Measures[1]	Project Timeframe C = Construction O = Operation X = Other		
				Past	Present	Future
Pollution (Section 3.1, Sediments and Water Quality)	Global	Common ocean pollutants are derived from land-based activities and include toxic compounds such as metals, pesticides, and other organic chemicals; excess nutrients from fertilizers and sewage; detergents; oil; plastics; and other solids. Pollutants enter oceans from non-point sources (stormwater runoff from watersheds), point sources (wastewater treatment plant discharges), other land-based sources (windblown debris), spills, dumping, vessels, and atmospheric deposition. Bilgewater is a mix of water, oily fluids, lubricants, grease, cleaning fluids, and other wastes that are pumped out periodically from vessel holding tanks, either to a reception facility onshore or treated with a bilge oil-separator and discharged at sea. Discharging sewage is largely prohibited under the Clean Water Act. The main risk of oil or other petroleum product spills is from ships, whether carrying petroleum to and from ports or in fuel tanks, and from pipelines and onshore facilities that transport and store oil and gas. CNMI has attempted to reduce the occurrence of pollution under Section 309 of the Coastal Zone Management Act as amended in 1990 and 1996, through the CNMI Department of Coastal Resources Management which implements fines and penalties for violators.		O	O	O
Climate Change (Section 3.2, Air Quality)	Global	Predictions of long-term negative environmental impacts, some of which have begun to occur at present, due to climate change include sea level rise; changes in ocean surface temperature, acidity/alkalinity, and salinity; changing weather patterns with increases in the severity of storms and droughts; changes to local and regional ecosystems (including the potential loss of species); shrinking glaciers and sea ice; thawing permafrost; a longer growing season; and shifts in plant and animal ranges, fecundity, and productivity. A special report by the Intergovernmental Panel on Climate Change discussed the long-term warming trend observed since pre-industrial times (Intergovernmental Panel on Climate Change, 2018), and how higher than the global annual average temperatures are being experienced in many		X	X	X

				Past	Present	Future
		land regions and seasons. An example of the increase in the severity of storms occurred in October 2018. Typhoon Yutu had sustained winds of 180 miles per hour, and was the Earth's 10th Category 5 storm of 2018. It was the biggest storm to hit U.S. soil since 1935, as two people were killed, hundreds were injured, and over 3,000 houses were destroyed. In the aftermath much of Saipan and Tinian went without power for weeks afterwards and had severe water shortages (Wong & Cruz, 2018).Anthropogenic greenhouse gas emissions have changed the physical and chemical properties of the oceans, including a 1-degree Celsius temperature rise, increased carbon dioxide absorption, decreased pH, alteration of carbonate chemistry, the decline in dissolved oxygen, and disruption of ocean circulation (Poloczanska et al., 2016). Observations of species responses that have been linked to anthropogenic climate change are widespread, and trends include shifts in species distribution to higher latitudes and deeper locations, earlier onset of spring and later arrival of fall, declines in calcification, and increases in the abundance of warm-water species. Climate change is expected to continue to impact the Study Area negatively and will contribute added stressors to all resources in the Study Area. CNMI has attempted to assess and mitigate the effects of climate change under Section 309 of the Coastal Zone Management Act as amended in 1990 and 1996, through the CNMI Department of Coastal Resources Management, through working groups and research.

				Past	Present	Future

[1] Some projects/activities did not list specific impacts minimization measures (such as avoidance techniques, standard operating procedures, or industry-best management practices) or mitigation requirements; either official documentation of project descriptions could not be obtained or did not specify these actions. In most cases, site-specific actions are to be developed as specific projects are developed.

Notes: CNMI = Commonwealth of the Northern Mariana Islands, EA = Environmental Assessment, EIS = Environmental Impact Statement, NOA = Notice of Availability, OEIS = Overseas Environmental Impact Statement, SCUBA = Self-Contained Underwater Breathing Apparatus, SEIS = Supplemental EIS, U.S. = United States, USAF = U.S. Air Force

4.3 Cumulative Impacts on Environmental Resources

Since the information available on past, present, and reasonably foreseeable actions varies in quality and level of detail, impacts of these actions were quantified where available data made it possible; otherwise, professional judgment was used to make a qualitative assessment of impacts. Due to the large scale of the area considered (the Study Area and overlapping areas of other actions) and multiple other activities interacting in the ocean environment (Table 4.2-1), the analysis of the incremental contribution to cumulative stress that the Proposed Action may have on a given resource is largely qualitative and speculative. Chapter 3 (Affected Environment and Environmental Consequences) includes a robust discussion of the "general threats," an analysis of aggregate project effects, and a broader level analysis specific to areas where impacts are concentrated (i.e., ranges/operating areas). The Chapter 3 (Affected Environment and Environmental Consequences) analysis is referenced and briefly summarized in each section below to provide context and perspective to the rationale for the conclusions that the Proposed Action would have an insignificant contribution to the cumulative stress experienced by these resources.

Cumulative impacts were analyzed for each resource addressed in Chapter 3 (Affected Environment and Environmental Consequences) for the Proposed Action in combination with past, present, and reasonably foreseeable future actions. The analysis was not separated by Alternative because the data available for the cumulative effects analysis was mostly qualitative and, from a landscape-level perspective, these qualitative impacts are expected to be similar.

Under Alternative 1 or Alternative 2 of the Proposed Action, the Navy would implement the mitigation detailed in Chapter 5 (Mitigation) to avoid or reduce impacts on biological, socioeconomic, and cultural resources in the Study Area.

4.4 Resource-Specific Cumulative Impacts

By CEQ guidance (Council on Environmental Quality, 1997), the following cumulative impacts analysis focuses on impacts that are "truly meaningful." The level of analysis for each resource is commensurate with the intensity of the impacts identified in Chapter 3 (Affected Environment and Environmental Consequences) and the level to which impacts from the Proposed Action are expected to mingle with impacts from existing activities. A full analysis of potential cumulative impacts is provided for marine mammals, marine invertebrates, sea turtles, and socioeconomic resources. The rationale is also provided for an abbreviated analysis of the following resources: sediments and water quality, air quality, marine habitats, marine birds, marine vegetation, fishes, cultural resources, terrestrial species and habitats, socioeconomic resources, and public health and safety.

4.4.1 Sediments and Water Quality

In the 2015 MITT Final EIS/OEIS, the analysis in Section 3.1 (Sediments and Water Quality) indicated that training and testing activities under each alternative could result in local, short- and long-term changes in sediment and water quality. However, chemical, physical, or biological changes remained within standards, regulations, and guidelines. The short-term impacts arose from explosions and the byproducts of explosions and combusted propellants. The analysis in the 2015 MITT Final EIS/OEIS determined that it was unlikely that these short-term impacts would overlap in time and space with other future actions that produce similar constituents. Therefore, the short-term impacts did not contribute to cumulative impacts.

The long-term impacts arose from unexploded ordnance, non-combusted propellant, metals, and other materials. Long-term impacts of each alternative are cumulative with other actions that cause increases in similar constituents. However, the contribution of Alternative 1 or Alternative 2 in the 2015 MITT Final EIS/OEIS to long-term cumulative impacts was determined to be negligible because of the following:

- Most training and testing activities are widely dispersed in space and time.
- Where activities are concentrated (i.e., Farallon de Medinilla [FDM]), marine habitat conditions observed over multiple years through dive studies indicate that ecological services that maintain water quality have not been inhibited at FDM.
- Most components of expended materials are inert or corrode slowly.
- Numerically, most of the metals expended are small- and medium-caliber projectiles, metals of concern comprise a small portion of the alloys used in expended materials, and metal corrosion is a slow process that allows for dilution.
- Most of the components are subject to a variety of physical, chemical, and biological processes that render them benign.
- Potential areas of impacts would be limited to small zones immediately adjacent to the explosive, metals, or chemicals.

Under this SEIS/OEIS, the contribution of proposed changes in training and testing activities under Alternative 1 or Alternative 2 would still be negligible based on the reasons presented above. While all of the additional projects since 2015 may be measurable and result in long-term and widespread changes in environmental conditions (e.g., nutrient loading, turbidity, salinity, or pH), any changes in sediment and water quality would be subject to applicable standards and guidelines. Given that impacts on water quality as a result of the proposed training and testing activities would be considered negligible, the incremental contribution to cumulative impacts on water quality would also be negligible.

4.4.2 Air Quality

In the 2015 MITT Final EIS/OEIS, the analysis in Section 3.2 (Air Quality) indicated that training and testing activities conducted under each alternative resulted in increased criteria pollutant emissions and hazardous air pollutant emissions throughout the Study Area. Sources of the emissions included vessels and aircraft and, to a lesser extent, munitions. Potential impacts included localized and temporarily elevated pollutant concentrations; however, recovery occurs quickly as emissions disperse. The analysis in the 2015 MITT Final EIS/OEIS concluded that the impacts of Alternatives 1 or 2 were cumulative with other actions that involve criteria air pollutant and hazardous air pollutant emissions. However, the incremental contributions, from implementing activities in accordance with the 2015 MITT Final EIS/OEIS Record of Decision (ROD), to cumulative impacts were low for the following reasons:

- Most training and testing activities-related emissions are projected to occur at distances greater than 3 nautical miles (NM) from shore.
- Few stationary offshore air pollutant emission sources exist within the Study Area, and few are expected in the foreseeable future.
- International regulations by the International Maritime Organization required commercial shipping vessels to switch to lower-sulfur fuel near U.S. and international coasts beginning in 2012 (National Oceanic and Atmospheric Administration 2011).

- The Department of Defense released the *Operational Energy Strategy: Implementation Plan*, which reduced demand, diversified energy sources, and integrated energy consideration into planning (Department of Defense 2012). Since then, the Navy has released the 2016 Operational Energy Strategy, which builds on the successes of the 2012 Operational Energy Strategy (U.S. Department of Defense, 2016).

Under this SEIS/OEIS, the contribution of proposed increases in training and testing activities under Alternative 1 or Alternative 2 would still result in low cumulative impacts based on the reasons presented above. In addition, the International Maritime Organization is set to impose a new 0.5 percent sulfur cap on marine fuel emissions (International Maritime Organization, 2017). Construction-related activities associated with the additional other projects in the area could generate increased air emissions; however, air quality in the region would not be significantly impacted due to the quick dispersive nature of emissions. Based on the analysis presented in Section 3.2 (Air Quality) of this SEIS/OEIS and the reasons summarized above, the incremental contribution of Alternatives 1 or 2 to cumulative impacts on air quality would not be significant.

In addition to the cumulative effects of criteria and hazardous air pollutants, greenhouse gas emissions would increase under the Proposed Action. Greenhouse gases contribute to climate change, which are felt on a global scale, rather than having localized effects. Although the Proposed Action would result in a decrease in greenhouse gas emissions, the Secretary of the Navy has released energy goals that aim to reduce the overall impact that the department has on climate change. Some of those goals involve using alternative energy sources for 50 percent of total consumption needs by 2020, having 50 percent of Navy and Marine Corps installations be net-zero emissions by 2020, and reducing petroleum use in the commercial fleet by 50 percent. These activities would more than offset the greenhouse gas emissions that would result from implementation of Alternative 1 or 2.

4.4.3 Marine Habitats

In the 2015 MITT Final EIS/OEIS, the analysis presented in Section 3.3 (Marine Habitats) indicated that marine habitats were affected by explosive stressors (underwater detonations) and physical disturbance or strikes (vessels and in-water devices, military expended materials, or seafloor devices). Impacts included localized disturbance of the seafloor, cratering of soft bottom sediments, and structural damage to hard bottom habitats. Impacts on soft bottom habitats were determined to be short term, and impacts on the hard bottom were determined to be long term. Alterations to marine habitats that occurred under the alternatives in the 2015 MITT Final EIS/OEIS were found to be additive to those associated with other actions. The relative incremental contributions, from implementing activities in accordance with the 2015 MITT Final EIS/OEIS ROD, to the overall alterations of marine habitats within the Study Area were low for the following reasons:

- As stated in the 2015 MITT Final EIS/OEIS, training activities utilizing bottom placed detonations would only occur in the existing underwater detonation areas at Piti, Agat, and Outer Apra Harbor. Cobble, rocky reef, and other hard bottom habitat may be scattered throughout the area, but those areas would be avoided during training to the maximum extent practicable.
- Impacts were confined to a limited area, and recovery of soft bottom habitats occurs quickly.

It can reasonably be assumed that there may be impacts on marine habitats from other actions such as seismic surveys and commercial fishing, but no specific details regarding the impacts or effects can be determined with any specificity or certainty. Seismic surveys and commercial fishing may occur in any open area of the Study Area. Seismic surveys could temporarily disturb soft bottom sediment and would

have no impacts on non-living hard-bottom habitats. Commercial fishing could temporarily disturb soft bottom sediment, and trawling or dragging the bottom of the seafloor could have moderately longer impacts on non-living hard-bottom habitats by movement of sediment; however, impacts would not change the nature of the habitat from non-living hard-bottom. For actions such as the Department of the Navy's Commonwealth of the Northern Mariana Islands Joint Military Training action, direct and indirect impacts could occur on Tinian; however, the Proposed Action is being revised to avoid or reduce direct impacts on marine habitats. Proposed training and testing activities under this SEIS/OEIS would result in minimal impacts on habitat on or around Tinian due to proposed activities such as amphibious assault; raid; noncombatant evacuation operation; humanitarian assistance/disaster relief operations; personnel insertion/extraction; parachute insertion; and intelligence, surveillance, and reconnaissance. These impacts would be minimal because proposed activities that could impact marine habitats, such as explosives, would not occur in the nearshore region of Tinian. Standard operating procedures, and mitigation measures would avoid or reduce impacts on marine habitat for the activities listed that occur near Tinian under the Proposed Action. Based on the analysis presented in Section 3.3 (Marine Habitats) and the reasons summarized above, the incremental contribution of Alternatives 1 or 2 to cumulative impacts would be negligible. Therefore, further analysis of cumulative impacts on marine habitats is not warranted.

4.4.4 Marine Mammals

4.4.4.1 Region of Influence

The range and habitat for marine mammals extends well beyond the Study Area boundaries and for some species represents only a portion of the full extent of the species' range during their life cycle. Baleen whales (e.g., humpback and blue whales) and some toothed whales (e.g., sperm whales and killer whales) seasonally migrate great distances, including into and out of the Study Area. Many of the smaller toothed whales do not migrate in the strictest sense, but some do undergo seasonal shifts in distribution both within and outside of the Study Area.

Table 3.4-1 lists the current abundance of marine mammal species in the Study Area and the general occurrence locations within the Study Area where they may be encountered. There are 26 marine mammal species known to exist in the Study Area, including 7 mysticetes (baleen whales) and 19 odontocetes (dolphins and toothed whales). Populations are varied; while the average population of certain dolphin and some whale populations include thousands of individuals, other stock populations are unknown or estimated to be in the hundreds. As with other marine resources, distribution is patchy and can be temporarily concentrated in specific areas depending on the species.

4.4.4.2 Resource Trends

Relevant information on the status, distribution, population trends, and ecology is presented for each species and stock in the Study Area in Section 3.4.1 (Affected Environment). The current aggregate impacts of past human activities are significant for some marine mammal species, many of which were in serious decline across the world's oceans. In the Pacific and specifically where the Navy has been intensively training and testing activities for decades, many marine mammal populations seem to be trending towards an increase in abundance.

4.4.4.3 Impacts of Other Actions

4.4.4.3.1 Overview

Section 3.4.1.7 (General Threats) discusses threats within the affected environment that impact marine mammal populations in the Study Area, including water quality degradation (chemical pollution), commercial industries (fisheries bycatch, explosive pest deterrents, and other interactions), noise, hunting, vessel strike, marine debris, disease and parasites, and climate change. Potential impacts of actions that affect marine mammals include mortality, injury, disturbance, and reduced fitness (e.g., reduced reproductive, foraging, and predator avoidance success). The susceptibility of marine mammals to these impacts often depends on proximity, severity, or vulnerability to the stressor, and vulnerability can be increased as multiple stressors compound on an individual.

The activities as described in Table 4.2-1 each potentially create multiple stressors in the Study Area experienced by marine mammals, including vessel traffic, underwater noise, and water pollution. For example, most Navy actions include marine vessel operations, which contribute to underwater noise and the risk of vessel strikes, but Navy vessels are a negligible fraction of the overall vessel presence and, thus, vessel noise in the Study Area. Tens of thousands of cargo vessels annually transit through the Study Area to and from ports in Asia as part of the global network of commercial ship movement (Kaluza et al., 2010). Many human activities also contribute underwater noise from sources other than vessels, including commercial fishing, seismic surveys, construction activities, and other military operations. Bycatch and entanglement, the main threats to marine mammal populations, are chiefly associated with fishing (National Marine Fisheries Service, 2016; Read et al., 2006). While Table 4.2-1 discusses these stressors for individual actions, their aggregate impacts specific to marine mammals are detailed in Section 3.4.1.7 (General Threats) and further described below. Data availability is inconsistent between species and activities, but quantitative estimations are presented where available.

4.4.4.3.2 Commercial Fishing

Several commercial foreign fisheries operate in the Study Area. Potential impacts from these activities include marine mammal injury and mortality due to bycatch and entanglement. Fisheries have also resulted in substantial changes to the structure and function of marine ecosystems that adversely affect marine mammals (National Marine Fisheries Service, 2016). As discussed below, future commercial fishing activities in the Study Area are expected to result in significant impacts on some marine mammal species based on the relatively high injury and mortality rates associated with bycatch and entanglement. This mortality could result in or contribute to population declines for some species. Ecological changes brought about by commercial fishing are also expected to adversely impact marine mammals in the Study Area.

4.4.4.3.2.1 Bycatch

Potential impacts from commercial fishing activities include marine mammal injury and mortality from bycatch, when animals are caught in commercial fishing operations targeting a different species. In 1994, the MMPA was amended to formally require the development of a take reduction plan when U.S. bycatch exceeds a level that is considered unsustainable by the marine mammal population and will lead to marine mammal population decline for U.S. stocks of marine mammals. Although marine mammal bycatch associated with U.S. fisheries has generally declined since the implementation of take reduction measures, and new management practices and consistent regulatory oversight could result in future reductions, this only affects U.S. fisheries; bycatch is expected to remain a leading cause of mortality for

the reasonably foreseeable future (Baker et al., 2006; Lent & Squires, 2017; Read et al., 2006; Song, 2017).

The potential biological removal level is the number of animals that can be removed each year without preventing a stock from reaching or maintaining its optimal sustainable population level. The impacts of bycatch on marine mammal populations vary based on removal rates, population size, and reproductive rates. Small populations with relatively low reproductive rates are most susceptible. At least in part as a result of the MMPA bycatch amendment, estimates of bycatch in the Pacific declined by a total of 96 percent from 1994 to 2006 (Geijer & Read, 2013). Cetacean bycatch declined by 85 percent from 342 in 1994 to 53 in 2006, and pinniped bycatch declined from 1,332 to 53 over the same time period.

Fisheries operations also result in substantial changes to the structure and function of marine ecosystems that adversely affect marine mammals, including loss of prey species and alteration of benthic structure. Overfishing of many fish stocks results in significant changes in trophic structure, species assemblages, and pathways of energy flow in marine ecosystems (Jackson et al., 2001; Myers & Worm, 2003). These ecological changes may have important, and likely adverse, consequences for populations of marine mammals (DeMaster et al., 2001). For instance, depletion of preferred prey could lead to a less-nutritious diet and decreased reproductive success.

4.4.4.3.2.2 Entanglement

As discussed in Section 3.4.1.7 (General Threats), entanglement in fishing gear, such as abandoned or partial nets, fishing line, and the ropes and lines connected to fishing gear, is another threat to marine mammals in the Study Area. The National Oceanic and Atmospheric Administration Marine Debris Program (2014) reports that abandoned, lost, or otherwise discarded fishing gear still constitutes the vast majority of mysticete entanglements.

4.4.4.3.2.3 Hunting

With the enactment of the MMPA, hunting-related mortality has decreased over the last 40 years; however, unregulated harvests and extensive legal and illegal whaling activity still occur in areas outside of U.S. waters. Between 1948 and 1979, the Union of Soviet Socialist Republics' whale harvest totaled 195,783 in the North Pacific Ocean. Subsistence harvest of marine mammals by Russian and Alaska Natives occurs in the North Pacific, Chukchi Sea, and Bering Sea, affecting marine mammal stocks that may be present in the Study Area.

4.4.4.3.3 Maritime Traffic and Vessel Strikes

Maritime traffic has increased over the past 50 years, and vessel traffic is expected to continue to increase in the Study Area due to continued economic globalization, widening of the Panama Canal, and increases in offshore energy development and other offshore activities (see for example (Kaluza et al., 2010)). While increased risks come with increased vessel traffic, risks of vessel strikes could be minimized by ongoing and future education and awareness, marine mammal reporting, and maritime traffic planning and management. The most vulnerable marine mammals are thought to be those that spend extended periods at the surface or species whose unresponsiveness to vessel sound makes them more susceptible to vessel collisions (Gerstein, 2002; Laist & Shaw, 2006; Nowacek et al., 2004). Marine mammals such as dolphins and porpoises, which can move quickly throughout the water column, are not as susceptible to vessel strikes.

4.4.4.3.4 Ocean Pollution

As discussed in Table 4.2-1, multiple pollutants from numerous sources are present in, and continue to be released into, the oceans. These releases that affect marine mammals include water pollution as well as the discharge of marine debris and the proliferation of ambient as well as impulsive noise in the underwater ecosystem. Section 3.4.1.7 (General Threats) provides an overview of these potential impacts, which include morbidity and mortality from acute toxicity (although mortality has not yet specifically been shown in marine mammals); disruption of endocrine cycles and developmental processes causing reproductive failures or birth defects; suppression of immune system function; and metabolic disorders resulting in cancer or genetic abnormalities (Reijnders et al., 2009). The effects of exposure to and concentration of persistent organic pollutants in marine mammals, especially from pesticides, includes the accumulation of dichlorodiphenyltrichloroethane (DDT) and polychlorinated biphenyls (PCBs) in certain species, and high concentrations of organochlorines in tissues appear to have occurred with increasing frequency, based on disease outbreaks involving marine mammals. In addition, experimental and other evidence has shown that persistent contaminants often found in the tissues of marine mammals have deleterious effects on reproduction and the immune system (O'Shea et al., 1999).

4.4.4.3.5 Ocean Noise

Ocean noise as a general stressor in modern oceans is described in Table 4.2-1 and as specific stressors to marine mammals in Section 3.4.1.7 (General Threats). Noise is of particular concern to marine mammals because many species use sound as a primary sense for navigating, finding prey, avoiding predators, and communicating with other individuals. Noise can cause behavioral disturbances; mask other sounds (including their own vocalizations); and may result in injury, including hearing loss in the form of temporary threshold shift or permanent threshold shift (PTS) or, in some cases, death.

Anthropogenic noise is generated from a variety of sources throughout the Study Area, including commercial shipping, oil and gas exploration and production activities (including air gun, drilling, and explosive decommissioning), commercial and recreational fishing (including vessel noise, fish-finding sonar, fathometers, acoustic deterrent, and harassment devices), shoreline construction projects (including pile driving), recreational boating and whale-watching activities, offshore power generation (including offshore windfarms), and research (including sound from air guns, sonar, and telemetry).

The military activities addressed in Table 4.2-1 include various training and testing operations that contribute vessel noise, in-water and in-air explosions, and sonar. While sonar activity can impact individual marine mammals, impacts on populations are not expected. Although various other training and testing activities involve surface or undersea detonations or gunnery exercises, these are generally mitigated through monitored exclusion zones and are infrequent, isolated events. As noted in Table 4.2-1, many activities incorporate best management practices or standard operating procedures to minimize noise generation; in particular, in-water construction at naval piers regularly utilizes dampening and attenuation technologies and other practices that reduce impacts on bottlenose dolphins and other sensitive receptors in the vicinity of pile-driving activities.

4.4.4.3.6 Marine Debris and Ingestion

Interactions between marine mammals and marine debris, including derelict fishing gear (as discussed in Section 4.4.4.3.2.2, Entanglement) and plastics, are significant sources of injury and mortality (Baulch & Perry, 2014), and the percentage of marine mammal species with documented records of entanglement in or ingestion of marine debris has increased from 43 to 66 percent over the past 18 years (Bergmann

et al., 2015). Ingestion of plastic bags and Styrofoam has been identified as a cause of injury or death of minke whales and deep-diving odontocetes, including beaked whales, pygmy sperm whales, pilot whales, and sperm whales.

4.4.4.3.7 Disease and Parasites

Section 3.4.1.7.8 (Disease and Parasites) discusses the effects of disease and parasites in marine mammals. Just like humans, older animals are more likely to be affected by disease and likewise can spread disease through a population, affecting a significant number of otherwise healthy individuals. Mass die-off events can also occur as a result of toxic algal blooms, which may be increasing in frequency due to human nutrient input and climate change, and the spread of certain parasites from the feces of feral cats (toxoplasmosis, hookworms, lungworms, and thorny-headed worms) to marine mammals in storm runoff.

4.4.4.4 Impacts of the Proposed Action that May Contribute to Cumulative Impacts

Impacts of the Proposed Action are detailed in Section 3.4 (Marine Mammals). Impacts that may contribute to cumulative impacts on marine mammals can be generally categorized as mortality, injury (Level A harassment under the MMPA), and behavioral responses and temporary threshold shift (TTS) (Level B harassment under the MMPA). These impacts would be associated with certain acoustic (sonar and other transducers), physical disturbance, and strike stressors. Although behavioral impacts are possible from the remaining stressors (as defined in Section 3.4.2, Environmental Consequences), these stressors are not expected to result in harassment, TTS, PTS, injury, or mortality of marine mammals.

The analysis presented in Section 3.4 (Marine Mammals) concluded that some stressors associated with the Proposed Action could impact individuals of certain marine mammal species, but impacts are not expected to decrease the overall fitness of any marine mammal population. Species most likely to be impacted by training and testing activities are dwarf sperm whales and pygmy sperm whales along with delphinids species (dolphins and small whales), which are the most abundant species in the Study Area. From a cumulative perspective, any potential impacts on species with small populations, especially Endangered Species Act (ESA)-listed species, are of particular concern, and the Navy has consulted with the National Marine Fisheries Service, as required by Section 7(a)(2) of the ESA, in that regard. The Navy will implement mitigation to avoid or reduce impacts from acoustic, explosive, and physical disturbance and strike stressors on marine mammals, as described in Chapter 5 (Mitigation).

As determined in Section 3.4 (Marine Mammals), it is not anticipated that the Proposed Action would result in significant impacts on marine mammal populations. The majority of the proposed activities are unit-level training and testing activities, which are conducted in the open ocean. Unit-level events occur over a small spatial scale (one to a few square miles) and with few participants (usually one or two) or short duration (the order of a few hours or less). Additionally, training and testing activities are generally separated in space and time in such a way that it would be unlikely that any individual marine mammal would be exposed to stressors from multiple activities within a short timeframe. Furthermore, research and monitoring efforts have included before, during, and after-event observations and surveys, data collection through conducting long-term studies in areas of Navy activity, occurrence surveys over large geographic areas, biopsy of animals occurring in areas of Navy activity, and tagging studies where animals are exposed to Navy stressors. To date, the findings from the research and monitoring and the regulatory conclusions from previous analyses by the National Marine Fisheries Service (NMFS) (National Marine Fisheries Service, 2015a; National Oceanic and Atmospheric Administration, 2013) are that the

majority of impacts from Navy training and testing activities are not expected to have deleterious impacts on the fitness of any individuals or long-term consequences to populations of marine mammals.

Mitigation measures discussed in Chapter 5 (Mitigation) are designed to avoid or reduce potential impacts of explosives, especially higher-order impacts such as injury and mortality to the greatest extent practicable. The acoustic analysis indicates that pressure waves resulting from explosive detonations would not lead to mortality for any of the marine mammals in the Study Area. The effectiveness of procedural mitigation measures is conservatively considered in the Navy's quantitative analysis process.

There are no records of a marine mammal ever being struck by a vessel during training and testing activities in the Study Area, and a vessel strike resulting from the Proposed Action is not anticipated.

4.4.4.5 Cumulative Impacts on Marine Mammals

As discussed above, fishery bycatch, vessel strikes, and entanglement in marine debris are leading causes of direct mortality to marine mammals (Carretta et al., 2017; Helker et al., 2017; Lent & Squires, 2017; National Marine Fisheries Service, 2016; National Oceanic and Atmospheric Administration Marine Debris Program, 2014; Read et al., 2006). Although Navy activities are mitigated to the greatest extent practicable, the Proposed Action could also result in injury and mortality to individuals of some marine mammal species from in-water explosions and vessel strikes. Implementation of measures discussed in Chapter 5 (Mitigation) would help avoid or reduce, but not absolutely eliminate, the risk for potential impacts, and any incidence of injury and mortality that might occur under the Proposed Action could be additive to injury and mortality associated with other actions in the Study Area. While it is more likely that an individual of an abundant, common stock or species would be affected, there is a chance that a less abundant stock could be affected.

Ocean noise, globally and specifically in the Study Area, is already significantly elevated over historic, natural levels, and acoustic stressors (in-water explosions and sonar, as well as increased Navy vessel noise) associated with the Proposed Action could also result in additive acoustic impacts on marine mammals. However, sonar is not known to make up a significant portion of the overall ocean noise budget (Bassett et al., 2010; Baumann-Pickering et al., 2010; International Council for the Exploration of the Sea, 2005; McDonald et al., 2006). Other current and future actions such as construction, and operation of offshore energy projects; seismic surveys; and construction, operation, and removal of offshore energy facilities could result in underwater sound levels that could cause behavioral harassment, TTS, PTS, or, to a less extent, injury or mortality. Additionally, the constant elevation in ambient noise may produce physiological stress in individuals to which the Proposed Action would contribute.

Sounds from many of these sources travel over long distances, and it is possible that some would overlap in time and space with sounds from in-water explosions or Navy sonar use, in particular commercial shipping noise, which is more widespread and continuous. It is not known whether the co-occurrence of shipping noise and sounds associated with in-water explosions and sonar use would result in harmful additive impacts on marine mammals. However, these training and testing activities are widely dispersed, the sound sources are intermittent, and mitigation measures would be implemented. Furthermore, standard operating procedures would preclude some training and testing activities in the immediate vicinity of other actions, further reducing the likelihood of simultaneous or overlapping exposure. For these reasons, it is unlikely that an individual marine mammal would be simultaneously exposed to sound levels from multiple actions that could cause behavioral harassment, TTS, PTS, or injury.

If the health of an individual marine mammal were compromised, it is possible this condition could alter the animal's expected response to stressors associated with the Proposed Action. The behavioral and physiological responses of any marine mammal to a potential stressor, such as underwater sound, could be influenced by various factors, including disease, dietary stress, body burden of toxic chemicals, energetic stress, percentage body fat, age, reproductive state, and social position. Synergistic impacts are also possible; for example, animals exposed to some chemicals may be more susceptible to noise-induced loss of hearing sensitivity (Fechter & Pouyatos, 2005). While the response of a previously stressed animal might be different from the response of an unstressed animal, no data are available at this time that accurately predict how stress caused by various ocean pollutants would alter a marine mammal's response to stressors associated with the Proposed Action.

In summary, the aggregate impacts of past, present, and other reasonably foreseeable future actions continue to have significant impacts on some marine mammal species in the Study Area. The Proposed Action could contribute incremental stressors to individuals, which would both further compound effects on a given individual already experiencing stress and, in turn, have the potential to further stress populations, some of which may already be in significant decline or in the midst of stabilization and recovery.

Furthermore, the regulatory process administered by NMFS, which includes Stock Assessments for all marine mammals, as well as five-year reviews for all ESA-listed species, provides a backstop that informs decisions on take authorizations and Biological Opinions. Stock Assessments include estimates of Potential Biological Removal that stocks of marine mammals can sustainably absorb. MMPA take authorizations require the minimization of adverse effects and are explicitly limited to small numbers, with no more than a negligible impact on species and stocks of marine mammals. MMPA authorizations are reinforced by monitoring and reporting requirements so that NMFS is kept informed of deviations from what has been approved. Biological Opinions for federal and non-federal actions are similarly grounded in status reviews and conditioned to avoid jeopardy and to allow continued progress toward recovery. These processes help to ensure that, through compliance with these regulatory requirements, the Navy's Proposed Actions would not have a measurable effect on the resource.

4.4.5 Sea Turtles

4.4.5.1 Region of Influence

The general region of influence for sea turtles includes open ocean and coastal water off Guam, Rota, Tinian, Saipan, and FDM. The 2015 MITT Final EIS/OEIS analyzes amphibious landings on the beaches of Guam, Rota, and Tinian where sea turtles are known to nest. As this SEIS/OEIS only addresses sea-based training and testing activities in the Study Area, the impacts of amphibious landings on sea turtle nesting and other land-based impacts of amphibious landings are not addressed or analyzed in this SEIS/OEIS. The sea turtle species occurring in the Study Area include green sea turtles (*Chelonia mydas*) (Central West Pacific DPS), hawksbill sea turtle (*Eretmochelys imbricata*), loggerhead sea turtle (*Caretta caretta*), olive ridley sea turtle (*Lepidochelys olivacea*), and leatherback sea turtle (*Dermochelys coriacea*). In general, sea turtles spend most of their time at sea, with female turtles returning to land to nest and often migrating long distances between feeding grounds and nesting beaches. As with other marine resources, distribution is patchy and can be concentrated in specific areas depending on the species, season, habitat, activity, and age of the individuals.

4.4.5.2 Resource Trends

All sea turtles in the Study Area have experienced significant decline in population numbers over the past hundred years and are ESA-listed (Table 3.5-1). Because sea turtles are so long-lived, and because reliable data are only available for approximately the past 20 years, it is not possible to determine a reliable trend in abundance for most species. In addition, leatherback sea turtles, loggerhead sea turtles, and olive ridley sea turtles are not expected to occur in nearshore waters of the Study Area, increasing the difficulty of tracking trends of these species in pelagic waters. Recent information, however, shows significant increases of green sea turtles and hawksbill sea turtles in nearshore waters of Guam. Jones and Martin (2016) analyzed five decades of aerial surveys (from 1962 through 2012), calculated a population growth rate of approximately 90 percent over the past five decades for these two species, and estimated that 85 percent of the sea turtles were green sea turtles, and 15 percent were hawksbill sea turtles. The Navy is currently funding in-water tagging of sea turtles to further understand resource trends in waters off of Guam, Tinian, and Saipan. Since November 2015 when tagging began, Falcone et al. (2017) report that the majority of sea turtles observed or captured (65 of 68 total sea turtles observed, or 96 percent) have been green sea turtles.

4.4.5.3 Impacts of Other Actions

4.4.5.3.1 Overview

Section 3.5.1.5 (General Threats) discusses the specific stressors within the affected environment that impact sea turtle populations in the Study Area, which include water quality (marine debris and chemical contaminants), commercial industries (fisheries bycatch and other interactions), hunting/exploitation, vessel strike, oil and gas development, wind energy development, shoreline development and recreation, dredging, military activities, invasive species, disease, habitat destruction (loss of seagrass habitat and nesting beaches), and climate change. Potential impacts of actions that affect sea turtles include mortality, injury, disturbance, and reduced fitness, including reproductive, foraging, and predator avoidance success.

The susceptibility of sea turtles to these outcomes often depends on proximity, severity, or vulnerability to the stressor, and vulnerability can be increased as multiple stressors compound on an individual. The abundance of the species, potential impacts that may affect localized nesting sites, and individual fatalities could have considerable impacts in localized populations.

The activities as described in Table 4.2-1 each potentially contribute multiple stressors in the Study Area experienced by sea turtles, including vessel traffic, underwater noise, and water pollution. For example, most actions include the operation of marine vessels, which contribute to vessel strikes and underwater noise. Bycatch and entanglement, among the main threats to sea turtle populations in the Study Area, are chiefly associated with fishing and are discussed separately. While Table 4.2-1 discusses these stressors for individual actions, their aggregate impacts specific to sea turtles are detailed in Section 3.5.1.5 (General Threats) and further described below.

4.4.5.3.2 Commercial Fishing and Harvest

Past and present commercial fishing activities have had a global effect on the recovery and conservation of marine turtle populations and, despite continued improvements in bycatch avoidance and the implementation of regulatory efforts, fisheries interactions continue to be the primary human-related source of mortality for most sea turtles (National Research Council of the National Academies, 1990; Wallace et al., 2010). Among fisheries that incidentally capture sea turtles, certain types of trawl, gillnet, and longline fisheries generally pose the greatest threat. One comprehensive study estimated that

worldwide, 447,000 turtles are killed each year from bycatch in commercial fisheries (Wallace et al., 2010). In United States' fisheries, bycatch resulted in 71,000 sea turtle deaths per year prior to effective protective sea turtle regulations (enacted in the mid-1990s); but current mortality estimates are 94 percent lower than pre-regulation estimates (Finkbeiner et al., 2011).

Globally, large-scale commercial exploitation also contributes to global decline in marine turtle populations. Currently, 42 countries and territories allow some form of take of turtles and collectively remove in excess of 42,000 turtles per year, the majority of which (more than 80 percent) are green sea turtles (Humber et al., 2014). Illegal fishing for turtles and nest harvesting also continues to be a major cause of sea turtle mortality, both in countries that allow sea turtle take and in countries that outlaw the practice (Lam et al., 2011; Maison et al., 2010). For example, Humber et al. (2014) estimated that 65,000 sea turtles have been illegally harvested in Mexico since 2000. The authors, however, have seen legal and illegal direct take of sea turtles trending downward over the past three decades—citing a more than 40 percent decline in green sea turtle take since the 1980s, a more than 60 percent decline in hawksbill and leatherback take, and a more than 30 percent decline in loggerhead take (Humber et al., 2014).

4.4.5.3.3 Maritime Traffic and Vessel Strikes

Maritime traffic has increased over the past 50 years, and vessel traffic is expected to continue to increase in the Study Area in response to continued economic globalization, increases in energy development, and other offshore activities. Vessel strike has been identified as one of the important mortality factors in several nearshore turtle habitats worldwide. Precise data are lacking for sea turtle mortalities directly caused by ship strikes; however, live and dead turtles are often found with deep cuts and fractures indicative of collision with a boat hull or propeller (Hazel et al., 2007; Lutcavage et al., 1997). Some vessel strikes could cause temporary impacts, such as diverting the turtle from its previous activity or causing minor injury. Major strikes could cause permanent injury or death from bleeding, infection, or inability to feed. Apart from the severity of the physical strike, the likelihood and rate of a turtle's recovery from a strike may be influenced by its age, reproductive state, and general condition. Numerous living sea turtles bear scars that appear to have been caused by propeller cuts or collisions with vessel hulls (Hazel et al., 2007; Lutcavage et al., 1997), suggesting that not all vessel strikes are lethal. While increased risks come with increased vessel traffic, risks of vessel strikes could be minimized by ongoing and future education and awareness, ship-speed reduction measures, and maritime traffic planning and management.

4.4.5.3.4 Coastal Land Development

Although sea turtle nesting sites within the Mariana Islands are not included in the Study Area for this SEIS/OEIS, impacts on sea turtle nesting sites from activities not associated with training and testing activities may impact overall populations of sea turtles within the region of influence for this SEIS/OEIS.

Female sea turtles migrate to their natal beaches to lay eggs, and pervasive coastal development often interferes with successful nesting at these locations. Shared use between turtles and human interests on increasingly populated and utilized beach areas has intensified the tendency for female turtles and their hatchlings to encounter various barriers and hazards accessing, nesting, and leaving these beaches. The following factors prevent beach access and emigration of sea turtles: beachfront construction of homes, hotels, restaurants, roads, seawalls, and shoreline armoring; beach erosion; ports and marinas; beach replenishment; nearshore dredging; and oil and gas activities. Beach-going vehicles and watercraft cause injury and mortality to sea turtles. Abandoned debris and equipment are often insurmountable obstacles for both mother and offspring (SeeTurtles.org, 2017). Populated areas also often have excess

nighttime lighting that confuses hatchlings' instincts to orient toward the moon to arrive at the ocean, and in this journey, they often fall into and can remain trapped within pits and scars left on the beach. Conservation awareness has increased on many popular U.S. beaches and tourist destinations, but nesting success remains imperiled in many others.

4.4.5.3.5 Ocean Pollution

As discussed in Table 4.2-1, multiple pollutants from numerous sources are present in, and continue to be released into, the oceans. Section 3.5.2 (Environmental Consequences) provides an overview of these potential impacts on sea turtles, which include the ingestion of and entanglement in marine debris as well as toxicity from bisphenol-A, phthalates, and heavy metals. Sea turtles often mistake debris for prey; one study found 37 percent of dead leatherback turtles had ingested various types of plastic (Mrosovsky et al., 2009). Other marine debris, including derelict fishing gear and cargo nets, can entangle and drown turtles in all life stages.

4.4.5.3.6 Ocean Noise

Ocean noise as a general stressor in modern oceans is described in Table 4.2-1. Anthropogenic noise is generated from a variety of sources throughout the Study Area, including commercial shipping, oil and gas exploration and production activities (including air gun, drilling, explosive decommissioning), commercial and recreational fishing (including vessel noise, fish-finding sonar, fathometers, acoustic deterrent and harassment devices), shoreline construction projects (including pile driving), recreational boating and whale-watching activities, offshore power generation (including offshore windfarms), and research (including sound from air guns, sonar, telemetry). The military activities addressed in Table 4.2-1 include various training and testing activities that also contribute vessel noise, in-air and in-water explosions, and sonar; however, due to the low risk of encounter and the implementation of required mitigation measures, the Surveillance Towed Array Sensor System Low Frequency Active Sonar training and testing activities are not expected to result in mortality to any sea turtles, and minimal injury or behavioral changes are anticipated.

In general, the potential concerns associated with ocean noise and sea turtles are not as well defined as those for marine mammals. While it is well known that many species of marine mammals use sound as a primary sense for navigating, finding prey, and communicating with other individuals, little is known about how sea turtles use sound in their environment. Based on knowledge of their sensory biology (Bartol & Musick, 2003; Bartol & Ketten, 2006; Ketten & Moein-Bartol, 2006; Levenson et al., 2004), there is evidence that sea turtles may be able to detect objects within the water column (e.g., vessels, prey, predators) via some combination of auditory and visual cues. However, research examining the ability of sea turtles to avoid collisions with vessels shows they may rely more on their vision than auditory cues (Hazel et al., 2007). Similarly, while sea turtles may rely on acoustic cues from breaking waves to identify nesting beaches, they also appear to rely on other non-acoustic cues for navigation, such as magnetic fields (Lohmann & Lohmann, 1992, 1996) and light (Avens, 2003). Additionally, sea turtles are not known to produce sounds underwater for communication. As a result, sound may play a limited role in a sea turtle's environment.

Nonetheless, as discussed in Section 3.5.2.1 (Acoustic Stressors), sea turtles could experience a range of impacts from ocean noise, depending on the sound source. The impacts could include permanent or temporary hearing loss, changes in behavior, physiological stress, and auditory masking. In addition, potential impacts from use of explosives could range from physical discomfort to non-lethal and lethal injuries.

4.4.5.4 Impacts of the Proposed Action That May Contribute to Cumulative Impacts

The cumulative impacts analysis includes green, hawksbill, olive ridley, leatherback, and loggerhead turtles, all of which are ESA-listed species. The analysis presented in Section 3.5 (Sea Turtles) concludes that some stressors associated with the Proposed Action could impact individuals of certain sea turtle species, but impacts are not expected to decrease the overall fitness of any sea turtle population. From a cumulative perspective, potential impacts on listed species are of particular concern, and mitigation measures designed to avoid or reduce the potential impacts are discussed in Chapter 5 (Mitigation).

Impacts from the Proposed Action that may contribute to cumulative impacts on sea turtles can be generally categorized as behavioral responses, temporary and PTSs, non-auditory injury (modeled as slight lung injury and gastrointestinal tract injury), and mortality. As summarized below, these impacts would be associated with certain acoustic and physical strike stressors. The use of sonar and other transducers may result in behavioral responses, and temporary and PTSs in sea turtles, including ESA-listed sea turtles. Explosives may result in behavioral responses, TTS, PTS, injury, and mortality in sea turtles, including ESA-listed sea turtles. Vessel strikes may cause injury or mortality in sea turtles, including ESA-listed sea turtles.

The remaining acoustic stressors (noise from air guns, weapons firing/launch/impact, aircraft overflight, vessels), energy stressors (electromagnetic, high energy lasers), physical disturbance and strike stressors (in-water devices, military expended materials, seafloor devices), entanglement stressors (cables, wires, decelerators/parachutes), ingestion stressors (military expended materials – munitions and military expended materials – other than munitions), and secondary stressors are not expected to result in temporary or PTSs, injury, or mortality of sea turtles under the Proposed Action, including ESA-listed sea turtles. The Proposed Action would not introduce significant light sources that would disorient nesting turtles or their hatchlings. Because the Navy's training and testing activities covered under this SEIS/OEIS do not co-occur with nesting activities, it is unlikely that stressors presented to sea turtles would contribute to other anthropogenic threats not caused by Navy activities.

Although sea turtles could be exposed to sound and energy from explosive detonations throughout the Study Area, the estimated impacts on individual sea turtles are unlikely to impact populations. Injured sea turtles could suffer reduced fitness and long-term survival. Sea turtles that experience temporary or PTSs may have reduced ability to detect relevant sounds such as predators or prey, although some with temporary threshold shift would recover quickly, possibly in a matter of minutes. It is uncertain whether some permanent hearing loss over a part of a sea turtle's hearing range would have long-term consequences for that individual because the sea turtle hearing range is already limited (Section 3.5.2.1, Acoustic Stressors). Any significant behavioral reactions to acoustic stimuli could lead to a sea turtle expending energy and missing opportunities to secure resources. However, most individuals are not likely to experience long-term consequences from behavioral reactions because exposures would be intermittent and widely spaced, allowing exposed individuals to recover. Since long-term consequences for most individuals are unlikely, long-term consequences for populations are not expected.

In summary and as determined in Section 3.5 (Sea Turtles), it is not anticipated that the Proposed Action would result in significant impacts on sea turtles. Due to the wide dispersion of stressors, speed of the platforms, and general dynamic movement of many training and testing activities, it is very unlikely that a sea turtle would remain in the potential impact range of multiple sources or sequential exercises. Additionally, the majority of the proposed activities are unit-level training and small testing activities, which are conducted in the open ocean. Unit-level exercises occur over a small spatial scale (one to a few square miles) and with few participants (usually one or two) or short duration (the order of a few

hours or less). Likewise, training and testing activities are generally separated in space and time in such a way that it would be unlikely that any individual sea turtle would be exposed to stressors from multiple activities within a short timeframe. Furthermore, research and monitoring efforts have included before, during, and after-event observations and surveys; data collection through conducting long-term studies in areas of Navy activity; occurrence surveys over large geographic areas; biopsy of animals occurring in areas of Navy activity; and tagging studies where animals are exposed to Navy stressors. To date, the findings from the research and monitoring and the regulatory conclusions from previous analyses by NMFS (National Marine Fisheries Service, 2015a; National Oceanic and Atmospheric Administration, 2013) are that majority of impacts from Navy training and testing activities are not expected to have deleterious impacts on the fitness of any individuals or long-term consequences to populations of sea turtles.

4.4.5.5 Cumulative Impacts on Sea Turtles

The fact that all five species of sea turtles occurring in the Study Area are ESA-listed provides a clear indication that the current aggregate impacts of past human activities are significant for sea turtles. Bycatch, vessel strikes, coastal land development, and ocean pollution are the leading causes of mortality and population decline for sea turtles, and, although mitigated/avoided to the greatest extent practicable, the Proposed Action could result in stress, injury, and mortality to individuals of some sea turtle species from in-water explosions and vessel strikes. Implementation of observation and delay measures discussed in Chapter 5 (Mitigation) would help avoid or reduce, but not absolutely eliminate, the risk for potential impacts, and any incidence of injury and mortality that might occur under the Proposed Action could be additive to injury and mortality associated with other actions in the Study Area.

According to scientific studies, sea turtles may rely primarily on senses other than hearing for interacting with their environment and appear to recover quickly from noise stressors (Section 3.5.2.1, Acoustic Stressors); thus, the acoustic stressors produced by Navy activities are anticipated to have minimal cumulative impact on sea turtles. The Proposed Action would not affect turtle nesting habitat, and contaminants and debris discharged into the marine environment are expected to be negligible and not persistent (Section 4.4.1, Sediments and Water Quality). Effects from the Proposed Action to sea turtle food sources are avoided or insignificant (Section 4.4.7, Marine Vegetation, and Section 4.4.8, Marine Invertebrates). Likewise, Navy actions generally would not overlap in space and time with other stressors as they occur as dispersed, infrequent, and isolated events that do not last for extended periods.

The potential exists for the impacts of ocean pollution (disease, malnourishment), injury, nesting habitat loss, starvation, and the composite increased underwater noise environment to contribute multiple stressors to an individual, and it is possible that the response of a previously stressed animal to impacts associated with the Proposed Action could be more severe than the response of an unstressed animal, or impacts from the Proposed Action could make an individual more susceptible to other stressors. For example, if a Navy vessel were to strike and injure an otherwise healthy sea turtle, exposure to multiple other stressors in the area may hinder the individual's recovery from any injury sustained in the accident. Likewise, a sea turtle near an in-water explosion or sonar activity may become stressed or disoriented, and the time to recover may be increased if that individual is likewise experiencing disease, malnutrition, or other strike injury that may increase its vulnerability to predation or decrease its ability to forage.

In summary, the aggregate impacts of past, present, and other reasonably foreseeable future actions continue to have significant impacts on all sea turtle species in the Study Area as evident by their scarce populations. The Proposed Action could contribute incremental stressors to individuals, which would both further compound effects on a given individual already experiencing stress and in turn has the potential to further stress populations in significant decline or recovery efforts thereof. Additionally, as with marine mammals, the NMFS regulatory process includes Stock Assessments and five-year reviews for all ESA-listed species, which provides a backstop that informs decisions on take authorizations and Biological Opinions. Biological Opinions for federal and non-federal actions are grounded in status reviews and conditioned to avoid jeopardy and to allow continued progress toward recovery. This process helps to ensure that, through compliance with these regulatory requirements, the Navy's Proposed Action would not have a measurable effect on the resource into the future.

4.4.6 Marine Birds

In the 2015 MITT Final EIS/OEIS, the analysis in Section 3.6 (Marine Birds) indicated that birds were impacted by acoustic stressors (sonar and other transducers, in-water explosions, weapons firing noise, aircraft noise, vessel noise), energy stressors (electromagnetic devices), physical disturbance and strikes (aircraft, aerial targets, vessels and in-water devices, military expended materials), and ingestion (military expended materials – munitions and military expended materials – other than munitions). Potential responses included a startle response, which includes short-term behavioral (e.g., movement) and physiological components (e.g., increased heart rate). Recovery from the impacts of most stressor exposures occurs quickly, and impacts are localized. Some stressors, including in-water explosions, physical strikes, and ingestion of plastic military expended materials, result in mortality. However, the number of individual birds affected was expected to be low, and no population-level impacts were expected. The impacts of the alternatives were determined to be cumulative with other actions that caused short-term behavioral and physiological impacts and mortality to birds. However, the incremental contribution of those alternatives to cumulative impacts on birds were determined to be low for the following reasons:

- Most of the proposed activities were widely dispersed in offshore areas, where bird distribution is patchy and concentrations of individuals are often low. Therefore, the potential for interactions between birds and training and testing activities was low.
- As discussed in Section 3.6 (Marine Birds), there have been no statistically significant declines in numbers of indicator species that nest on FDM, despite a long history of military use of FDM.
- It is unlikely that training and testing activities influenced nesting because most activities take place in water and away from nesting habitats on land. Alternatives 1 or 2 did not result in destruction or loss of nesting habitat.
- For most stressors, impacts were short term and localized, and recovery occurs quickly.
- While a limited amount of mortality could occur, no population-level impacts were expected.
- None of the alternatives were likely to adversely affect ESA-listed bird species.

Under this SEIS/OEIS, the contribution of proposed increases in training and testing activities under Alternative 1 or Alternative 2 would still be negligible based on the reasons presented above. While all of the additional projects since 2015 may be measurable and contribute to the cumulative impacts on marine birds, the number of individual marine birds affected is expected to be low, and no population-level impacts are expected. Based on the analysis presented in Section 3.6 (Marine Birds)

and the reasons summarized above, the incremental contribution of Alternatives 1 or 2 to cumulative impacts would be negligible. Further analysis of cumulative impacts on marine birds is not warranted.

4.4.7 Marine Vegetation

In the 2015 MITT Final EIS/OEIS, the analysis presented in Section 3.7 (Marine Vegetation) indicated that marine vegetation was affected by explosive stressors (in-water explosions), physical stressors (vessels and in-water devices, military expended materials, or seafloor devices), and secondary stressors (impacts associated with sediments and water quality) and is still valid in this SEIS/OEIS analysis. Potential impacts included localized disturbance and mortality. As discussed in the 2015 MITT Final EIS/OEIS, the analysis indicated that recovery would occur quickly, and population-level impacts were not anticipated. Impacts of the alternatives in the 2015 MITT Final EIS/OEIS were considered to be cumulative with other actions that caused disturbance and mortality of marine vegetation.

The current aggregate impacts of past, present, and reasonably foreseeable future actions presented in Table 4.2-1 may affect marine vegetation. Aggregate impacts from vessel movement, increased sedimentation, and other stressors associated with other actions discussed in Table 4.2-1 could result in injury and mortality. Although this SEIS/OEIS does address some of these projects, developments, and actions listed in Table 4.2-1, many of these other actions and their associated cumulative impacts on marine vegetation cannot be determined with any specificity or certainty. However, it can reasonably be assumed that there may be marine vegetation that could be affected by these actions, but no specific details are known regarding the impacts or effects to individuals or populations. Alternatives 1 or 2 could also result in injury and mortality to marine vegetation from in-water explosions and strikes. Injury and mortality that might occur would be additive to injury and mortality associated with other actions. However, the relative contribution of Alternatives 1 or 2 to the overall injury and mortality would be low compared to other actions for the following reasons:

- Most training and testing activities would occur in areas where seagrasses and other attached marine vegetation do not grow.
- Impacts would be localized, recovery would occur quickly, and no population-level impacts would be expected.
- Proposed training and testing activities would not result in impacts that have historically affected marine vegetation. For example, Alternatives 1 or 2 would not increase nutrient loading, which can cause algal blooms, decrease light penetration, and impact photosynthesis of seagrasses.

Under this SEIS/OEIS, the contribution of proposed increases in training and testing activities under Alternative 1 or Alternative 2 would still be low, based on the reasons presented above. Impacts on marine vegetation from projects such as pollution, and climate change could result in long-term or widespread changes in secondary stressors to the environment that would change environmental conditions, such as turbidity, salinity, pH, or water temperature that would impact marine vegetation. However, these impacts are expected to be localized, recovery would occur quickly, and no population-level impacts would be expected. Based on the analysis presented in Section 3.7 (Marine Vegetation) and the reasons summarized above, the incremental contribution of Alternatives 1 or 2 to cumulative impacts on marine vegetation would be negligible. Therefore, further analysis of cumulative impacts on marine vegetation is not warranted.

4.4.8 Marine Invertebrates

4.4.8.1 Region of Influence

The region of influence for invertebrates includes the entire Study Area as invertebrates occur in all habitats and depths, including both the water column and benthic habitat, and many species have pelagic larvae, such as corals, that can drift in the ocean currents until they settle on reefs. Invertebrate groups in the Study Area are listed in Section 3.8 (Marine Invertebrates) and include microscopic zooplankton that drift with currents (e.g., invertebrate larvae, copepods, protozoans), larger invertebrates living in the water column (e.g., jellyfish, shrimp, squid), and benthic invertebrates that live on or in the seafloor (e.g., clams, corals, crabs, worms).

4.4.8.2 Resource Trends

As discussed in Section 3.8.1.2 (General Threats), marine invertebrates are ecologically and economically crucial, performing essential ecosystem services such as coastal protection, nutrient recycling, food for other animals, and habitat, as well as providing income from tourism and commercial fisheries. The health and abundance of marine invertebrates are vital to the marine ecosystem and the sustainability of the world's fisheries. Invertebrates are fished for food (e.g., shrimps, lobsters, and crabs; scallops, clams, and oysters; sea urchins, sea cucumbers, squids, and octopuses); harvested for jewelry, curios, and the aquarium trade; and some are known to secrete medicinal compounds of interest to the health industry.

Corals occur throughout the Study Area and include three species (*Acropora globicep*s, *A. retusa*, and *Seriatopora aculeata*) that are listed under the ESA. Raymundo et al. (2017) reported a catastrophic mass mortality event of more than 50 percent in shallow staghorn (*Acropora*) coral in Guam that was initiated in 2013 by anomalous warm sea surface temperatures.

In 2017, NMFS determined that seven species of giant clam (*Hippopus, H. porcellanus, Tridacna costata, T. derasa, T. gigas, T. squamosa*, and *T. tevoroa*) were candidates that may warrant listing under the ESA (82 Federal Register 28946). A status review is currently being done for these species. Two species, *H. hippopus* and *T. gigas*, have historically been found in the Study Area but are believed to have been locally extirpated (Meadows, 2016).

4.4.8.3 Impacts of Other Actions

Section 3.8.1.2 (General Threats) includes an extensive discussion of the existing stressors to marine invertebrates, including overexploitation and destructive fishing practices, habitat degradation resulting from pollution and coastal development, disease, invasive species, oil spills, noise, global climate change, and ocean acidification. Tourism and recreation also pose threats to marine invertebrates. Beaches such as Chulu Beach, when not used for training, are open to the public, who may disturb or potentially injure marine invertebrates and nearshore hard bottom habitat. Stressors specific to reef-building corals, which are generally located in more shallow zones with adequate sunlight penetration and a mean annual water temperature more than about 64 degrees Fahrenheit, include thermal stress, disease, tropical storms, coastal development and pollution, erosion and sedimentation, tourism/recreation, fishing, trade in coral and live reef species, vessel anchoring or groundings, marine debris, predation, invasive species, and hydrocarbon exploration. Primary threats to deep-water or cold-water corals include bottom fishing, hydrocarbon exploration and extraction, petroleum contamination, cable and pipeline installation, and other various bottom-disturbing activities. Deep corals are susceptible to physical disturbance due to the branching and fragile growth form of some species, slow growth rate (colonies can be hundreds of years old), and low reproduction and recruitment rates. All

activities described in Table 4.2-1 have the potential to impact marine invertebrates due to their ubiquitous presence and relative vulnerability.

4.4.8.3.1 Climate Change

The primary threat to corals is global climate change, which has and is projected to continue to seriously impact coral reefs in the near and known future. The effects of climate change include increased water temperature, ocean acidification, increased frequency or intensity of cyclonic storm events, and sea level rise, which can cause direct damage to these crucial and sensitive ecosystems as well as increase their susceptibility to and decrease their resilience from encounters with all other threats, including disease, pathogens, and genetic disorders.

Increases in ocean temperature can lead to coral stress, bleaching, and mortality. Coral and other marine invertebrate (e.g., anemones, giant clams) bleaching, which occurs when corals expel the symbiotic algae living in their tissues, is a stress response often tied to atypically high sea temperatures or changes in light availability but also can be attributed to nutrients, toxicants, and pathogens (National Oceanic and Atmospheric Administration, 2017). Bleaching events have increased in frequency in recent decades, and coral bleaching on a global scale has occurred during the summers of 2014, 2015, and 2016. Likewise, ocean acidification has the potential to reduce calcification and growth rates in species with calcium carbonate skeletons, including shellfish, corals, and sponges, and possibly even lobsters and sea cucumbers. In addition to physical effects, increased acidity may result in behavioral changes in some species, such as burrowing behavior and juvenile dispersal patterns of the soft-shell clam and reduction in the loudness and number of snaps in the snapping shrimp.

Although the potential effects that climate change could have on future storm activity are uncertain, numerous researchers suggest that rising temperatures could result in little change to the overall number of storms, but that storm intensity could increase. Increased storm intensity could result in increased physical damage to individual corals and reefs constructed by the corals (which support numerous other invertebrate taxa), overturning of coral colonies, and a decrease in structural complexity (due to disproportionate breakage of branching species). However, large storms such as hurricanes may also have positive impacts on corals, such as lowering the water temperature and removing less resilient macroalgae from reef structures, which can overgrow corals.

Sea level rise could affect invertebrates by modifying or eliminating habitat, particularly estuarine and intertidal habitats bordering steep and artificially hardened shorelines. Likewise, changes in ocean circulation patterns could affect the planktonic food supply of filter- and suspension-feeding invertebrates. Cumulative effects of threats from fishing, pollution, and other human disturbance may reduce the tolerance of corals and other invertebrates to global climate change.

4.4.8.4 Impacts of the Proposed Action That May Contribute to Cumulative Impacts

The analysis presented in Section 3.8 (Marine Invertebrates) indicates that the Proposed Action could impact marine invertebrates through acoustic stressors (sonar and other transducers, air guns, vessel noise, weapons noise), explosives, energy stressors (in-water electromagnetic devices, high-energy lasers), physical disturbance or strikes (vessels and in-water devices, military expended materials, seafloor devices, pile driving), entanglement (wires and cables, decelerators/parachutes), and ingestion of military expended materials. Potential impacts include short-term behavioral and physiological responses (Celi et al., 2015; Edmonds et al., 2016; Roberts et al., 2016). Some stressors could also result in injury or mortality to a relatively small number of individuals. The potential for impacts on ESA-listed corals would be avoided by mitigation designed to avoid locations where they are present, except at

vital designated locations and nearshore training areas where seafloor resources will be avoided to the maximum extent practicable. For example, the Navy will not conduct certain activities within a specified distance of shallow-water coral reefs, live hard bottom, artificial reefs, and shipwrecks (Chapter 5, Mitigation) as much as is practicable. Employment of these measures will help avoid or reduce potential impacts on invertebrates that inhabit these areas.

4.4.8.5 Cumulative Impacts on Marine Invertebrates

Some direct impacts on invertebrates are expected, and the impacts of the Proposed Action could be cumulative with other actions that cause disturbance and mortality of marine invertebrates. However, it is anticipated that the incremental contribution of the proposed alternatives would be insignificant for the following reasons:

- Invertebrates are generally abundant and relatively short-lived; thus, with the exception of sessile species located near areas of repeated Navy activities (e.g., pierside locations), few individuals would likely be affected repeatedly by the same event.
- Invertebrates generally have high reproductive rates, short reproductive cycles, and resilient dispersal mechanisms; thus, local communities are likely to reestablish quickly.
- Most of the proposed activities would occur over dispersed, deep water areas where marine invertebrates are more sparsely distributed but not at the same specific point each time and, therefore, would be unlikely to affect the same individual invertebrates.
- Marine invertebrates are not particularly susceptible to energy, entanglement, or ingestion stressors resulting from Navy activities, and none of the alternatives would result in or interact with impacts that have been historically significant to marine invertebrates, such as overfishing, nutrient loading, disease, or the presence of invasive species.
- None of the alternatives would result in long-term or widespread changes in environmental conditions, such as turbidity, salinity, pH, or water temperature that could impact marine habitats or interact with existing trends affecting these parameters.
- The Navy will not conduct certain activities within a specified distance of shallow coral reefs, live hard bottom, artificial reefs, or submerged cultural resources such as shipwrecks (except designated locations, where these resources will be avoided to the maximum extent practicable). Underwater detonations that would occur in the nearshore areas are only conducted in designated locations and away from known seafloor resources such as shallow coral reefs, live hard bottom, artificial reefs, or submerged cultural resources such as shipwrecks, to the maximum extent practicable. All features that have been identified are included in Chapter 5 (Mitigation).

Although the aggregate impacts of other stressors in the ocean environment continue to have significant impacts on some marine invertebrate species in the Study Area, particularly the effects of global climate change on corals, the Proposed Action is not likely to incrementally contribute to population-level stress and decline of the resource. Due to the effects of global climate change, corals may be less resilient to additional stressors; however, it is not anticipated that the Navy will cause direct effects to coral reef systems. As impacts would be isolated, localized, and not likely to overlap with other relevant stressors, it is anticipated that the incremental contribution of the Proposed Action, when added to the impacts of all other past, present and reasonably foreseeable future actions, would not result in measurable additional impacts on marine invertebrates in the Study Area or beyond.

4.4.9 Marine Fishes

In the 2015 MITT Final EIS/OEIS, the analysis presented in Section 3.9 (Fishes) indicated that fishes, including ESA-listed scalloped hammerhead sharks, oceanic whitetip sharks, and giant manta rays could be affected by acoustic stressors (sonar and other transducers, explosives, swimmer defense air guns; weapons firing, launch, and impact noise; aircraft noise; and vessel noise), energy (electromagnetic devices), physical disturbance or strikes (vessels and in-water devices, military expended materials, seafloor devices), entanglement (fiber optic cables and guidance wires, decelerator/parachutes), and ingestion (military expended materials – munitions and military expended materials – other than munitions) and remains valid in this SEIS/OEIS.

Overfishing is discussed as a threat to marine fishes in the Study Area in the socioeconomic resources analysis in this SEIS/OEIS (Section 3.12.1.4.1.1, Guam; and 3.12.1.4.1.2, Commonwealth of the Northern Mariana Islands). While target fish species may be less available, which may have a greater impact on the success of traditional practices like subsistence fishing, overall traditional fishing practices on Guam and in the Commonwealth of the Northern Mariana Islands have not changed appreciably since the 2015 MITT Final EIS/OEIS, and the analysis in the 2015 MITT Final EIS/OEIS remains valid. Refer to Section 3.12.2.3 (Subsistence Use) of the 2015 MITT Final EIS/OEIS for a discussion of subsistence fishing practices on Guam and in the Commonwealth of the Northern Mariana Islands.

The current aggregate impacts of past, present, and reasonably foreseeable future actions presented in Section 4.2 (Projects and Other Activities Analyzed for Cumulative Impacts) may potentially affect fishes, including ESA-listed scalloped hammerhead sharks, oceanic whitetip sharks, and giant manta rays. Aggregate impacts associated with the other actions discussed in Section 4.2 (Projects and Other Activities Analyzed for Cumulative Impacts) and Table 4.2-1 could result in injury and mortality. Although this SEIS/OEIS does address some of these other actions listed in Section 4.2 (Projects and Other Activities Analyzed for Cumulative Impacts), many of these actions and their associated cumulative impacts on fish cannot be determined with any specificity or certainty at this time. However, it can reasonably be assumed that there may be fish that could be affected by these other actions, but no specific details are known regarding the impacts or effects to individuals or populations. Alternatives 1 or 2 could also result in injury and mortality to fish from in-water explosions, entanglement, and strikes. Injury and mortality that might occur under Alternatives 1 or 2 would be additive to injury and mortality associated with other actions. However, the relative contribution of Alternatives 1 or 2 to the overall injury and mortality would be low compared to other actions for the following reasons:

- Most potential impacts would be short-term behavioral and physiological responses.
- Any impacts from the Proposed Action resulting in injury or mortality would be to a relatively small number of individuals.
- No population-level impacts are anticipated.

Under this SEIS/OEIS, the contribution of proposed increases in training and testing activities under Alternative 1 or Alternative 2 would still be negligible based on the reasons presented above. Based on the analysis presented in Section 3.9 (Fishes) and the reasons summarized above, the incremental contribution of Alternatives 1 or 2 to cumulative impacts would be negligible. Further analysis of cumulative impacts on fishes is not warranted.

4.4.10 Terrestrial Species and Habitats

The only terrestrial location included in the region of influence for this SEIS/OEIS is FDM. Military use of FDM as a bombing range has occurred for decades, with the lease agreement formalized with the newly formed CNMI in 1983 (United States of America and Commonwealth of the Northern Mariana Islands, 1983). Since the late 1990s, the Navy has established restrictions on the types of ordnance used on FDM and where ordnance can be targeted in compliance with past biological opinions and Sikes Act obligations. These measures confine the impacts on discrete impact zones on the island, in contrast to island-wide targeting prior to the establishment of restrictions. By establishing these restrictions, the impacts of decades of military use of the island are reduced (e.g., not targeting a remnant forest patch on the north end of the island and allowing its recovery), and current and future ordnance use on the island are confined to discrete impact zones on the island. The activities that only occur on FDM other than training activities described in this SEIS/OEIS and the 2015 MITT Final EIS/OEIS include: (1) biennial range maintenance activities and periodic ordnance cleanup actions (U.S. Department of the Navy, 2013), and (2) ecological monitoring of natural resources on the island. Both of these activities are interrelated. For example, range clearance activities are required to maintain a suitable training environment on the range (e.g., ordnance cleanup, target maintenance). Surveys are conducted on the island in compliance with biological opinions and Sikes Act obligations associated with military use of the island. All of these activities are authorized and scheduled by the Navy, and entrance rights are conveyed to the Navy through the lease agreement with CNMI. In summary, there are no additional actions that would occur on FDM; therefore, an analysis of cumulative impacts is not warranted.

4.4.11 Cultural Resources

In the 2015 MITT Final EIS/OEIS, Alternatives 1 or 2 concluded that physical disturbance and strike stressors including vessel strikes, use of towed in-water devices, use of seafloor devices, and ground disturbance during training and testing activities would not adversely affect historic properties within U.S. territorial waters or on Guam and the Commonwealth of the Northern Mariana Islands because measures have been previously implemented to protect these resources and would continue to be implemented according to the conservation measures and procedures identified and described in the 2009 Mariana Islands Range Complex Programmatic Agreement.

The contribution of proposed increases in training and testing activities under Alternative 1 or Alternative 2 in this SEIS/OEIS would be negligible because the Navy routinely avoids locations of known obstructions, which includes submerged cultural resources, to prevent damage to sensitive Navy equipment and vessels and to avoid or reduce impacts on known submerged resources. The current aggregate impacts of past, present, and reasonably foreseeable future actions presented in Section 4.2 (Projects and Other Activities Analyzed for Cumulative Impacts) may have an effect on cultural resources. Actions that would contribute to cumulative impacts on cultural resources would involve some form of disturbance to the ocean bottom in areas where cultural resources are present. Actions that would disturb the ocean bottom could impact submerged cultural resources if those resources are not avoided.

Other actions that result in ocean bottom disturbance require federal agencies to take into account the effects of their undertakings on historic properties. If it is determined that there would be an adverse effect to a cultural resource that qualifies for the National Register, the federal agency would work to avoid, minimize, or mitigate the adverse effect. For example, the Bureau of Ocean Energy Management has procedures in place to identify the probability of the presence of submerged historic properties

shoreward from the 148-foot (45-meter) isobaths, informing the Navy to avoid locations of known obstructions, which includes submerged cultural resources. It also has procedures for project redesign or relocation to avoid identified resources (Minerals Management Service, 2007). Nonetheless, inadvertent impacts could occur if submerged cultural resources are present, but are greatly reduced when avoidance measures are put in place.

Effects to submerged historic properties from other actions would typically be avoided or mitigated through compliance with federal regulations. However, impacts could occur if avoidance measures were not implemented or if inadvertent disturbance or destruction of the characteristics or the historic property that qualify it for inclusion on the National Register occurs. Disturbance or destruction of submerged historic properties, including shipwrecks, would diminish the overall record for these properties and decrease the potential for meaningful research. When considered with other actions, Alternatives 1 or 2 would not contribute to cumulative impacts on submerged historic properties because the Navy avoids locations of known obstructions, which includes submerged cultural resources.

4.4.12 Socioeconomic Resources

In Section 3.12 (Socioeconomic Resources) of the 2015 MITT Final EIS/OEIS, the analysis determined that training and testing activities under Alternatives 1 or 2 would limit public access to certain nearshore areas used for commercial and recreational fishing, certain tourism activities, and subsistence fishing. However, limits on accessibility to these areas were not expected to significantly impact socioeconomic resources, because the majority of restrictions would be temporary, lasting hours, with the exception of the 3 NM danger zone surrounding FDM, which is permanently closed to ensure public safety. Other surface danger zones and temporary exclusion areas would be accessible to the public for fishing, transiting, or other activities when military activities are not occurring. When an area is closed for a training and testing activity, mariners are not permitted to transit directly through a danger zone to a destination outside of the danger zone and are not allowed to anchor or loiter within the danger zone. Military activities utilizing the danger zone or restricted area would be halted until the danger zone or restricted area is cleared of transiting vessels.

Under this SEIS/OEIS, cumulative impacts on fishing may occur from frequent or extended, but also temporary, closures of restricted areas and danger zones in the Study Area. The Navy attempts to mitigate these impacts by using a variety of communication methods (e.g., Notices to Mariners [NOTMARs], e-mails, Facebook posts) to inform the public of upcoming events that may limit access to certain areas. Dates and times of scheduled closures are provided in announcements to allow fishers, tour boat operators, and any other commercial or recreational vessels that may be in the area to plan accordingly.

As a result of previous discussions with fishers, the Navy no longer restricts access to the northern portion of W-517 while military activities are conducted in the southern portion of the warning area, which allows fishers to access popular fishing sites south of Guam. The fishing bank areas (Galvez Bank, Santa Rosa Reef, and White Tuna Banks) are not automatically restricted from public access when W-517 is scheduled for training and testing. Galvez Bank and Santa Rosa Reef are not within W-517, while a portion of White Tuna Banks does exist within W-517. Mariners near Galvez Bank or Santa Rosa Reef may be warned of their proximity or told not to enter W-517 as a precautionary measure. It is vital that units training or testing within W-517 give proper notice to mariners and aviators in the area before they enter W-517, in order to keep members of the public and military safe. On days that W-517 is in use for military training or testing that affects mariners, a Broadcast Notice to Mariners is always sent by

the U.S. Coast Guard to inform the public, in addition to press releases and other communication from Joint Region Marianas. The 120-day average (over a two-year period) that Broadcast Notice to Mariners (NOTMARS) are issued does not constitute 24 hours in the day. Many training or testing events last less than a full day and may hinder access to W-517 for only a short period of time.

The Navy also informs the public of extended periods of time when the restricted area (beyond 3 NM from shore) surrounding FDM will be accessible. The military will continue to collaborate with local communities and stakeholders to develop efficient and effective communication with the public. The goals of these on-going and evolving efforts are (1) to reduce socioeconomic impacts associated with limiting access to areas used by the public, and (2) to ensure the safety of the public and military personnel. Under this SEIS/OEIS, the contribution of proposed increases in training and testing activities under Alternative 1 or Alternative 2 would still be negligible based on the analysis summarized above and described in greater detail in the 2015 MITT Final EIS/OEIS, Section 3.12 (Socioeconomic Resources and Environmental Justice).

4.4.12.1 Resource Trends

Trends in commercial transportation and shipping are described in Section 3.12.1.1 (Commercial Transportation and Shipping) and indicate that commercial shipping has remained consistent over the past five years. Trends in commercial fishing and tourism are described in Section 3.12.1.2 (Commercial and Recreational Fishing) and Section 3.12.1.3 (Tourism), respectively. Commercial fisheries landing in Guam declined steadily from 2010 through 2015 mainly due to the declining abundance of reef fish around the island, which make up a large percentage of the target species (Weijerman et al., 2016). Trends in commercial fisheries around the CNMI are less clear. Landings from 2010 through 2015 were highest in 2013 and 2014 but declined to their lowest totals in 2015. Tourism trends are mixed for both Guam and the CNMI. The number of visitors from Japan, the largest market, has been declining in recent years, but tourism from other Asian nations, particularly China, has increased and is expected to continue to grow. Trends in recreational fishing are partially driven by trends in tourism. While both recreational fishing and subsistence fishing by residents of Guam and the CNMI remain popular, there are no data that indicate specific trends in either resource.

4.4.12.2 Onshore and Offshore Fishing for Economic Self-Sustainability

NMFS is responsible for the regulation and enforcement of policies for onshore and offshore fishing for economic self-sustainability. Both the CNMI and Guam are categorized as “fishing communities” by the Western Pacific Regional Fishery Management Council. This designation is based on the portion of the population that is dependent upon fishing for subsistence; the economic importance of fishery resources to the islands; and the geographic, demographic, and cultural attributes of the communities (Western Pacific Regional Fishery Management Council, 2009, 2019). Fishing is an integral part of the culture and way of life in the CNMI and Guam. Most fishers do not fish exclusively for commercial, recreational, or subsistence benefit but rather for some combination of the three (Hospital & Beavers, 2012; Hospital & Beavers, 2014; Tibbats & Flores, 2012; Western Pacific Regional Fishery Management Council, 2019). However, the increasing costs of fishing gear, tackle, boats and associated maintenance, and particularly fuel have made it increasingly difficult for fishers in Guam and the CNMI to make a living as commercial fishers. In addition to costs, fishers are concerned about impacts associated with increased tourism (e.g., pollution and damage to reefs) and competition from foreign fishers reducing the market for locally caught fish (Ayers, 2018; Hospital & Beavers, 2014; Western Pacific Regional Fishery Management Council, 2019). Fishing will continue as an integral part of the culture and tradition

of communities on Guam and in the CNMI; however, commercial productivity is likely to vary with changes in the local and global economies.

4.4.12.3 Impacts of Other Actions

The impacts of actions related to coastal development and infrastructure development listed in Table 4.2-1 would generally contribute positively to socioeconomic conditions on Guam and in the CNMI. Water quality and wastewater treatment on Saipan should improve; additional jobs in tourism and retail are likely with further coastal development; and tourism, the largest economic driver, should also be supported by these projects. Other military activities that limit access to popular fishing sites could increase cumulative socioeconomic impacts on commercial, recreational, and subsistence fishers beyond impacts associated with the Proposed Action. Increases in marine debris and pollution (Table 4.2-1) in waters surrounding Guam and the CNMI would potentially impact tourism and fisheries and contribute to cumulative impacts on socioeconomic resources or restrict vessel movement in the Study Area. The effects of climate change on the marine environment could have similar, long-term, cumulative impacts on fisheries and tourism in the region if the marine resources that support these industries are diminished.

4.4.12.4 Cumulative Impacts on Socioeconomic Resources

The current aggregate impacts of past, present, and reasonably foreseeable future actions have the potential to result in significant cumulative impacts on certain socioeconomic resources in the Study Area. The impacts would be considered significant if they resulted in extensive limitations on accessibility by residents, businesses, and tourists to ocean areas needed for commercial, recreational, and subsistence fishing and tourism. If tourism continues to expand, the desire to transit to and access popular ocean areas may also increase. Maintaining efficient and effective communication methods with the public is expected to avoid or reduce conflicts between military and civilian activities in the Study Area.

4.4.13 Public Health and Safety

In the 2015 MITT Final EIS/OEIS, the analysis presented in Section 3.13 (Public Health and Safety) indicated that the impacts of Alternatives 1 or 2 on public health and safety would be negligible. Under this SEIS/OEIS, Alternatives 1 or 2 are not expected to contribute incrementally to cumulative health and safety impacts. Therefore, further analysis of cumulative impacts on public health and safety is not warranted.

4.5 Summary of Cumulative Impacts

Marine mammals, marine invertebrates, sea turtles, and socioeconomic resources are the primary resources of concern for cumulative impacts analysis:

- Past human activities have impacted these resources to the extent that several marine mammals, sea turtles, and marine invertebrates occurring in the Study Area are ESA listed. Several marine mammal species and stocks are also classified as strategic stocks under MMPA.
- The use of sonar and other non-impulsive sound sources under Alternative 1 and Alternative 2 has the potential to disturb or injure marine mammals and sea turtles.
- Explosive detonations under Alternative 1 and Alternative 2 have the potential to disturb, injure, or kill marine mammal, and sea turtle species.
- Under Alternative 1 or Alternative 2, proposed danger zones could potentially restrict access to fishing and recreational areas when ranges are in use.

In summary, based on the analysis presented in Sections 3.4 (Marine Mammals), 3.5 (Sea Turtles), 3.8 (Marine Invertebrates), and 3.12 (Socioeconomic Resources and Economic Justice), the current aggregate impacts of past, present, and other reasonably foreseeable future actions are not significantly different than the assessment in the 2015 MITT Final EIS/OEIS. For marine mammals, sea turtles, and marine invertebrates Alternatives 1 or 2 would contribute to an increase cumulative impacts, but the relative contribution would be low compared to other actions. Cumulative effects on socioeconomic resources may have short-term impacts on accessibility to public services, fishing sites, and tourism resources, but they are not expected to have long-term negative impacts on these resources or the economy of Guam and the CNMI. No new information or circumstances are significant enough to warrant further cumulative impact review.

4.6 Public Comments

The public raised a number of issues during the scoping period in regard to cumulative impacts. The issues are summarized in the list below. Comments received from the public during the Draft Supplemental EIS (SEIS)/OEIS commenting period related to cumulative impacts are addressed in Appendix K (Public Comment Responses).

- **Analyze the cumulative effects of all Department of Defense actions in the Mariana Islands, including CNMI Joint Military Training EIS –** The CNMI Joint Military Training EIS would establish a series of live-fire and maneuver ranges and training areas within the CNMI and include amphibious operations on Tinian. The proposed action for the CNMI Joint Military Training EIS is to expand existing ranges and training areas and construct new ranges and training areas within the CNMI. The resources evaluated that could contribute to cumulative impacts include geology and soils, water resources, air quality, noise, airspace, land and submerged land use, recreation, terrestrial biology, marine biology, cultural resources, visual resources, transportation, utilities, socioeconomic resources and environmental justice, hazardous materials and waste, and public health and safety. The Navy is drafting a revised EIS that would reduce impacts on resources as a result of the proposed action. The analysis of cumulative impacts contained in this chapter addresses cumulative effects of all Department of Defense actions on the Mariana Islands, including the CNMI Joint Military Training EIS.
- **Cumulative impacts from military-expended material and debris on water quality and marine biology –** The analysis of cumulative impacts on water quality from military expended material and debris concluded that although military expended material would occur in the Study Area as a result of training and testing activities, the Navy has defined standard operating procedures and committed to mitigation measures to offset potential impacts from military training and testing to sediment and water quality in the Study Area. The impact analysis conducted on marine biology (e.g., marine mammals, sea turtles, marine birds, marine vegetation, marine invertebrates, and fish) from military expended material and debris concluded that the military expended material and debris would not have a significant impact on water quality or habitat, therefore it would not have a significant impact on marine biology in the Study Area. Further analysis of cumulative impacts on water quality can be found in Section 4.4.1 (Sediments and Water Quality). Further analysis of cumulative impacts on marine biology can be found in Sections 4.4.4 through 4.4.9 (Marine Mammals, Sea Turtles, Marine Birds, Marine Vegetation, Marine Invertebrates, and Marine Fishes).
- **Cumulative impacts on marine mammals from use of explosives and sonar –** The cumulative impact analysis for marine mammals from the use of explosives and sonar concluded that the aggregate impacts of past, present, and other reasonably foreseeable future actions continue to

have significant impacts on some marine mammal species in the Study Area. Proposed training and testing activities could result in additional stressors to individuals, which would both further compound effects on a given individual already experiencing stress and, in turn, have the potential to further stress populations, some of which may already be in significant decline or in the midst of stabilization and recovery. However, implementation of standard operating procedures would reduce the likelihood of overlap in time and space with other stressors, and implementation of mitigation measures would further reduce the likelihood of impact. Therefore, the incremental stressors anticipated from proposed training and testing activities are not anticipated to be significant. Further analysis of cumulative impacts on marine mammals can be found in Section 4.4.4 (Marine Mammals).

- Cumulative impacts on seagrass, coral reef, and other invertebrate from sedimentation around FDM, military expended materials as marine debris, and sonar disrupting larval recruitment – The cumulative impact analysis on seagrass and marine vegetation concludes that sedimentation around FDM and military expended materials as marine debris would have minimal impacts on seagrass and marine vegetation in the Study Area. Based on the analysis presented in Section 3.7 (Marine Vegetation) and the reasons summarized above, the incremental contribution of Alternatives 1 or 2 to cumulative impacts would be negligible. Further cumulative impact analysis on seagrass and marine vegetation can be found in Section 4.4.7 (Marine Vegetation). The cumulative impact analysis on coral reef and other invertebrates from sedimentation around FDM, military expended materials as marine debris, and sonar disrupting larval recruitment concluded that although the aggregate impacts of other stressors in the ocean environment continue to have significant impacts on some marine invertebrate species in the Study Area, particularly the effects of global climate change on corals, proposed training and testing activities are not likely to incrementally contribute to population-level stress and decline of the resource. Further cumulative impact analysis on marine invertebrates can be found in Section 4.4.8 (Marine Invertebrates).
- **Cumulative impacts on sea turtles, fish populations and their habitat –** The cumulative impacts analysis on sea turtles concluded that the aggregate impacts of past, present, and other reasonably foreseeable future actions continue to have significant impacts on all sea turtle species in the Study Area. Proposed training and testing activities could contribute incremental stressors to individuals, which would both further compound effects on a given individual already experiencing stress and in turn has the potential to further stress populations in significant decline or recovery efforts thereof. The cumulative impacts analysis on fish populations concluded that based on the analysis presented in Section 3.9 (Fishes) and the reasons summarized above, the incremental contribution of Alternatives 1 or 2 to cumulative impacts would be negligible. The cumulative impacts analysis on marine habitat concluded that based on the analysis presented in Section 3.3 (Marine Habitats) and the reasons summarized in Section 4.4.3 (Marine Habitats), the incremental contribution of Alternatives 1 or 2 to cumulative impacts would be negligible. Further analysis for cumulative impacts on sea turtles and fish can be found in Section 4.4.5 (Sea Turtles) and 4.4.9 (Marine Fishes) respectively.
- **Cumulative impact on the loss of access to FDM for traditional fishing practices –** The socioeconomic resources section analyzes traditional fishing practices that were identified by residents of Guam and the CNMI as having the potential to be impacted by the proposed training and testing activities occurring at sea and on FDM. Training and testing activities have the potential to temporarily limit access to areas of the ocean, which has the potential to impact traditional fishing practice in the Study Area. The military requests that the U.S. Coast Guard issue NOTMARs to warn the public of upcoming training and testing activities requiring the

exclusive use of sea space and to ensure the safety of the public and military personnel. Data on the number of NOTMARs issued from the years 2013 through 2017 for FDM and W-517 were added to the previous three years of data presented in the 2015 MITT Final EIS/OEIS. The number of days affected by activities occurring at FDM and W-517 has varied over the eight-year period from the years 2010 through 2017. The data indicate an increasing trend in affected days and potential impacts on accessibility; however, the peak totals are not substantially different from the previous eight years, and the trend appears to be cyclical (increases followed by decreases). Access to waters around FDM between 3 and 12 NM was restricted for an average of 160 days per year (peak of 201 in the year 2012), and access to waters under W-517 was restricted for an average of 91 days per year (peak of 136 in the year 2016). Access to waters within 3 NM of FDM is restricted at all times to ensure public safety during military activities using explosive munitions (33 Code of Federal Regulations 334, Danger Zone and Restricted Area Regulations).

Traditional fishers in Guam and the CNMI would also be impacted by temporary restrictions limiting access to certain areas where traditional fishing practices take place. As described in Section 3.12.1.4.1 (Traditional Fishing Practices), many fishers identifying as traditional fishers also participate in recreational and commercial fishing, and it is not clear when fishers are engaging in traditional fishing, which has communal and cultural significance, and when they are fishing for financial gain or leisure or some combination of one or more of these motivations, which can occur even on a single fishing trip (Allen, 2013). These data suggest that traditional fishing likely occurs in the same locations as commercial and recreational fishing, and that traditional fishers would not be disproportionately impacted by temporary limits on access to fishing sites. Other fishing sites in the Study Area would be available to traditional fishers, and significant impacts on traditional fishing in the Study Area are not anticipated. Further cumulative analysis for socioeconomic resources can be found in Section 4.4.12 (Socioeconomic Resources).

- Cumulative impact on reduced fishing access, recreational fishing, commercial fishing and transport between the Mariana Islands from the restricted areas – Access to certain areas of the Study Area around islands and in the open ocean is temporarily restricted during potentially hazardous training and testing activities to ensure the safety of the public and military personnel. Danger zones may result from other Department of Defense actions in Guam and the Mariana Islands such as the Guam and Commonwealth of the Northern Mariana Islands Military Relocation and CNMI Joint Military Training. These other actions would occur mainly on land and around Tinian. As a result of the training and testing activities associated with this SEIS/OEIS, areas within 3 NM of FDM are permanently restricted to maintain public safety. Even when hazardous activities are not occurring at FDM, the potential occurrence of unexploded ordnance in waters surrounding the island is a constant threat to public safety. Transiting between Guam, Saipan, Tinian, or other islands located to the south of FDM and the Islands Unit (Northern Mariana Islands) would potentially be impacted by limiting access to the 12 NM danger zone around FDM. Considering that an average of 3.8 trips per year has occurred over the past 30 years (as stated in Section 3.12.3, Public Scoping Comments), the probability of military activities interfering with trips to the Islands Unit is low. Furthermore, the military will announce when FDM is not in use in addition to notifying mariners of planned activities at FDM, which will enable mariners to better plan trips to the Islands Unit. Further analysis can be found for recreational and commercial fishing and transport in Section 4.4.12 (Socioeconomic Resources).

- **Cumulative effects analysis of the ocean as an ecosystem –** The cumulative impacts analysis for water resources concluded that based on the analysis presented in Section 3.1 (Sediments and Water Quality) and the reasons summarized above, the changes in sediment and water quality would be measurable, but would still be below applicable standards and guidelines; therefore, the incremental contribution of Alternatives 1 or 2 to cumulative impacts would be low and further analysis of cumulative impacts is not warranted. Further analysis of the ocean as an ecosystem and cumulative impacts can be found in Section 4.4.1 (Sediments and Water Quality) and Section 4.4.3 (Marine Habitats).
- **Assess cumulative effects to consider a resource response to change and capacity to withstand stress –** Stressors are considered in the cumulative effects analysis for each resource. These resources are analyzed in Sections 4.4.1 through 4.4.13.

  Cumulative effects analysis should reflect the beach landing activity addressed in the 2015 MITT ROD (no Amphibious Assault Vehicle or Landing Craft Air Cushion landing on Tinian beaches) – Beach landing activities would continue as discussed in the 2015 MITT Final EIS/OEIS. This SEIS/OEIS is an update to the in-water activities in the Study Area. Land activities are addressed in the 2015 MITT Final EIS/OEIS and can be found in Section 3.5 (Sea Turtles) of that document.

  Cumulative impacts assessing the length and frequency of each individual training activity and the potential rate of resource recovery – The cumulative impacts assessment takes into account the length and frequency of each training and testing activity and resource recovery as they are analyzed in their individual resource sections (Sections 3.1 through 3.13).
- **Utilize Caltrans/Federal Highways Administration cumulative impacts methodology/eight-step process –** The Caltrans/Federal Highways Administration cumulative impacts eight-step methodology is very similar to the cumulative impacts chapter analysis used in this document. The similarities are as follows: (step 1) The Navy has identified resources to consider; (step 2) defined the region of influence for each resource; (step 3) described the current health and historical context of each resource in Chapter 3 (Affected Environment and Environmental Consequences); (step 4) identified the direct and indirect impacts of the Proposed Action in the Environmental Consequences section of Chapter 3; (step 5) identified current and reasonably foreseeable future actions or projects in Table 4.2-1; (step 6) assessed the potential cumulative impacts in this chapter; (step 7) reported the results of the cumulative impact analysis in this chapter; and (step 8) assessed the need for mitigation and recommendations for actions by other agencies in Chapter 5 (Mitigation).

5 Mitigation

5.1 Introduction

This chapter describes the mitigation measures that the United States (U.S.) Department of the Navy (Navy) will implement to avoid or reduce potential impacts from the Mariana Islands Training and Testing (MITT) Supplemental Environmental Impact Statement (SEIS)/Overseas Environmental Impact Statement (OEIS) Proposed Action. This chapter has been updated in its entirety since Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the 2015 MITT Final Environmental Impact Statement (EIS)/OEIS (U.S. Department of the Navy, 2015). This Final SEIS/OEIS was prepared in coordination with the U.S. Air Force and U.S. Coast Guard, and these Services will implement applicable mitigation measures developed by the Navy for the Proposed Action. Under the Proposed Action, military readiness activities would be conducted at sea or on Farallon de Medinilla (FDM). Therefore, several mitigation measures developed for the 2015 MITT Final EIS/OEIS, such as mitigation for invasive species control and training activities conducted on the islands of Guam, Rota, Tinian, and Saipan, are outside the scope of this Final SEIS/OEIS. The Navy will continue implementing these mitigation measures in accordance with the U.S. Fish and Wildlife Service (2015) Biological Opinion. For additional information, see Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the 2015 MITT Final EIS/OEIS.

The Navy will also implement standard operating procedures specific to training and testing activities conducted under the Proposed Action. In many cases, standard operating procedures provide a benefit to environmental and cultural resources, some of which have high socioeconomic value in the Study Area. Standard operating procedures differ from mitigation measures because standard operating procedures are designed to provide for safety and mission success, whereas mitigation measures are designed specifically to avoid or reduce potential environmental impacts. An example of a standard operating procedure is that ships operated by or for the Navy have personnel assigned to stand watch at all times when underway. Watch personnel monitor their assigned sectors for any indication of danger to the ship and the personnel on board, such as a floating or partially submerged object or piece of debris, periscope, surfaced submarine, wisp of smoke, flash of light, or surface disturbance. The Navy also avoids known navigation hazards that appear on navigational charts, such as submerged wrecks and obstructions. As a standard collision avoidance procedure, watch personnel monitor for marine mammals that have the potential to be in the direct path of the ship. The standard operating procedures to avoid collision hazards are designed for safety of the ship and the personnel on board. This is different from mitigation measures for vessel movement, which require vessels to maneuver to avoid marine mammals by specified distances to avoid or reduce the potential for physical disturbance and strike of marine mammals, as described in Section 5.3.4.1 (Vessel Movement). In this example, the benefit of the mitigation measure for vessel movement is additive to the benefit of the standard operating procedure for vessel safety. Standard operating procedures that apply to the Proposed Action and are generally consistent with those included in the 2015 MITT Final EIS/OEIS are described in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of that document. Standard operating procedures that apply to the Proposed Action and were not included in, or require a clarification from, the 2015 MITT Final EIS/OEIS are discussed in Section 2.3.3 (Standard Operating Procedures) of this Final SEIS/OEIS.

In addition to the mitigation measures and standard operating procedures specific to the Proposed Action, the Navy has existing routine operating instructions (e.g., training manuals), local installation

instructions (e.g., Integrated Natural Resource Management Plans), and Programmatic Agreements that were developed to meet other safety and environmental compliance requirements or initiatives. For example, the Naval Air Training and Operating Procedures Standardization (NATOPS) General Flight and Operating Instructions Manual (CNAF M-3710.7) contains naval air training procedures pertaining to safe operations of aircraft, which includes requirements to minimize the disturbance of wildlife. Aviation units are required to avoid noise-sensitive areas, such as breeding farms, resorts, beaches, national parks, national monuments, and national recreational areas when at altitudes less than 3,000 ft. above ground level except when in compliance with applicable Federal Aviation Administration or U.S. Navy-approved traffic patterns, routes, or special use airspace (e.g., military operations areas). They are also required to avoid disturbing wild fowl in their natural habitats and to avoid firing directly at large fish, whales, or other wildlife.

Additionally, a Programmatic Agreement regarding military training in the Marianas contained procedures pertaining to military readiness activities and other Department of Defense projects (U.S. Department of Defense, 2009). For example, the Navy agreed to avoid certain training exercises within particular areas. Applicable maps have been updated annually and disseminated to military planners who coordinate and execute training exercises. As described in Section 3.11 (Cultural Resources), the 2009 Programmatic Agreement expired in December 2019. The Navy has executed an interim Programmatic Agreement to follow the exact terms of the 2009 agreement while a new agreement is being developed. In accordance with the terms of the Programmatic Agreement, if previously unknown cultural resources are discovered during applicable activities, the Navy will notify the appropriate Cultural Resources Manager and implement reasonable measures to avoid, minimize, or mitigate impacts to those resources. These requirements are in addition to mitigation measures developed for the Proposed Action. The Navy will continue complying with applicable operating instructions, local installation instructions, and Programmatic Agreements within the Study Area, as appropriate.

5.1.1 Benefits of Mitigation

The Chapter 3 (Affected Environment and Environmental Consequences) environmental analyses indicate that certain acoustic, explosive, and physical disturbance and strike stressors have the potential to impact certain biological or cultural resources. The Navy developed mitigation measures for those stressors and would implement the mitigation for either action alternative. The Navy considered the benefits of mitigation in the environmental analyses for both Alternative 1 and Alternative 2 of the Proposed Action in this Final SEIS/OEIS. In addition to analyzing mitigation measures pursuant to the National Environmental Policy Act (NEPA), the Navy designed its mitigation measures to achieve one or more benefits, such as the following:

- Effect the least practicable adverse impact on marine mammal species or stocks and their habitat, and have a negligible impact on marine mammal species and stocks (as required under the Marine Mammal Protection Act [MMPA]);
- Ensure that the Proposed Action does not jeopardize the continued existence of endangered or threatened species (as required under the Endangered Species Act [ESA]);
- Avoid or minimize adverse effects on essential fish habitat (as required under the Magnuson-Stevens Fishery Conservation and Management Act); and
- Avoid adversely impacting shipwrecks (as required under the Abandoned Shipwreck Act and National Historic Preservation Act).

In addition to the benefits listed above, certain mitigation measures would also benefit other species in the Study Area, such as seabirds listed under the Migratory Bird Treaty Act. The Navy coordinated its mitigation with the appropriate regulatory agencies, including the National Marine Fisheries Service (NMFS), through the consultation and permitting processes. The Navy Record of Decision will document all mitigation measures the Navy will implement under the Proposed Action. The NMFS Record of Decision, MMPA Regulations and Letter of Authorization, ESA Biological Opinion, and other applicable consultation documents will include the mitigation measures applicable to the resources for which the Navy has consulted. The suite of mitigation measures included in this Final SEIS/OEIS represents the maximum level of mitigation that is practical for the Navy to implement when balanced against impacts on safety, sustainability, and the ability to continue meeting its mission requirements. Should the Navy require a change in how it implements mitigation based on national security concerns, evolving readiness requirements, or other factors (e.g., significant changes in the best available science), the Navy will engage the appropriate agencies and reevaluate its mitigation through adaptive management or the appropriate consultations. The Navy's adaptive management approach is discussed in Section 5.1.2.2.1.1 (Adaptive Management). This approach was coordinated with NMFS during the consultation and permitting processes and will be included in the MMPA Regulations and Letter of Authorization.

5.1.2 Compliance Initiatives

To disseminate its mitigation requirements to the appropriate personnel and meet other compliance requirements for the MMPA and ESA, the Navy will continue using the Protective Measures Assessment Protocol and its ongoing monitoring and reporting initiatives, as described in the sections below.

5.1.2.1 Protective Measures Assessment Protocol

To disseminate requirements to the personnel who are required to implement mitigation during training and testing activities, the Navy will continue inputting its mitigation measures into the Protective Measures Assessment Protocol and appropriate governing instructions. The Protective Measures Assessment Protocol is a software tool that serves as the Navy's comprehensive data source for at-sea mitigation. The software tool provides personnel with notification of the required mitigation measures and a visual display of the planned training or testing activity location overlaid with relevant environmental data (e.g., mapped locations of shallow-water coral reefs). Navy policy requires applicable personnel to access the Protective Measures Assessment Protocol during the event planning process. This helps ensure that personnel receive mitigation instructions prior to the start of training and testing activities and that mitigation is implemented appropriately.

5.1.2.2 Monitoring, Research, and Reporting Initiatives

Many of the Navy's monitoring programs, research programs, and reporting initiatives have been ongoing for more than a decade and will continue as a compliance requirement for the MMPA or ESA, or both. The Navy and NMFS use the information contained within monitoring, research, activity, and incident reports when evaluating the effectiveness and practicality of mitigation and determining if adaptive adjustments to mitigation may be appropriate. These reports also facilitate better understandings of the biological resources that inhabit the Study Area and the potential impacts of the Proposed Action on those resources.

5.1.2.2.1 Marine Species Research and Monitoring Programs

Through its marine species research and monitoring programs, the Navy is one of the nation's largest sponsors of scientific research on and monitoring of marine species. Detailed information on these programs is provided in Section 3.0.1.1.1 (Marine Species Monitoring and Research Programs). Navy

research programs focus on investments in basic and applied research that increase fundamental knowledge and advance naval technological capabilities. Navy monitoring programs focus on the potential impacts of training and testing activities on biological resources. Monitoring reports are available to the public on the U.S. Navy's Marine Species Monitoring webpage (https://www.navymarinespeciesmonitoring.us/). The Navy will post future reports online as they become available.

Specific details regarding the content of the reports were coordinated with the appropriate agencies through the consultation and permitting processes. For this Final SEIS/OEIS, the Navy agreed to several additional research and monitoring initiatives designed to help advance the understanding of beaked whales and strandings in the MITT Study Area, including:

- Co-funding the Pacific Marine Assessment Program for Protected Species (PACMAPPS) Mariana Islands survey in spring-summer 2021 to help document beaked whale occurrence, abundance, and distribution in the Mariana Islands. This effort will include deployments of a towed array as well as floating passive acoustic buoys.
- Continuing to fund additional stranding response and necropsy analyses for the Pacific Islands region.
- Funding research on a framework to improve the analysis of single and mass stranding events, including the development of more advanced statistical methods to better characterize uncertainty associated with data parameters.
- Increasing analysis for any future beaked whale strandings in the Mariana Islands, to include detailed Navy reviews of available records of sonar use.
- Sponsoring beaked whale occurrence monitoring within select portions of the MITT Study Area starting in 2022, so as to not duplicate the 2021 PACMAPPS efforts described above.
- Including Cuvier's beaked whales as a priority species for analysis under a 2020-2023 Navy research funded program titled Marine Species Monitoring for Potential Consequences of Disturbance (MSM4PCOD). MSM4PCOD will explore how Navy-funded monitoring priorities can be adjusted to provide the best scientific information to support Population Consequence of Disturbance analysis.
- Funding and co-organizing with NMFS an expert panel to provide recommendations on scientific data gaps and uncertainties for further protective measure consideration to minimize potential impacts of Navy training and testing activities on beaked whales in the Mariana Islands.

Additional information about the U.S. Navy's Marine Species Monitoring Program, including its adaptive management and strategic planning components, is provided in the sections below.

5.1.2.2.1.1 Adaptive Management

Adaptive management is an iterative process of decision-making that accounts for changes in the environment and scientific understanding over time through a system of monitoring and feedback. Within the natural resource management community, adaptive management involves ongoing, real-time learning and knowledge creation, both in a substantive sense and in terms of the adaptive process itself (Williams et al., 2009). Adaptive management focuses on learning and adapting, through partnerships of natural resource managers, scientists, and other stakeholders. Adaptive management helps managers maintain flexibility in their decisions and provides them the latitude to change direction

to improve understanding of ecological systems and achieve management objectives. Taking action to improve progress toward desired outcomes is another function of adaptive management.

The Navy's adaptive management review process and reporting requirements serve as the basis for evaluating performance and compliance. The process involves technical review meetings and ongoing discussions between the Navy, NMFS, the Marine Mammal Commission, and other experts in the scientific community. An example of a revision to the compliance monitoring structure as a result of adaptive management is the development of the Strategic Planning Process, which is a planning tool for the selection and management of monitoring investments (U.S. Department of the Navy, 2013a). Through adaptive management, the Strategic Planning Process has been incorporated into the Integrated Comprehensive Monitoring Program, which is described below.

5.1.2.2.1.2 Integrated Comprehensive Monitoring Program

The Navy developed an Integrated Comprehensive Monitoring Program to serve as the overarching framework for coordinating its marine species monitoring efforts and as a planning tool to focus its monitoring priorities pursuant to ESA and MMPA requirements (U.S. Department of the Navy, 2010). The purpose of the Integrated Comprehensive Monitoring Program is to coordinate monitoring efforts across regions and to allocate the most appropriate level and type of monitoring effort for each range complex based on a set of standardized objectives, regional expertise, and resource availability. The Integrated Comprehensive Monitoring Program does not identify specific field-work or individual projects. It is designed to provide a flexible, scalable, and adaptable framework using adaptive management and the Strategic Planning Process to periodically assess progress and reevaluate objectives.

The Integrated Comprehensive Monitoring Program is evaluated through the adaptive management review process to (1) assess progress, (2) provide a matrix of goals and objectives, and (3) make recommendations for refinement and analysis of monitoring and mitigation techniques. This process includes conducting an annual adaptive management review meeting where the Navy and NMFS jointly consider the prior year's goals, project results, and related scientific advances to determine if monitoring plan modifications are warranted to address program goals more effectively. Modifications to the Integrated Comprehensive Monitoring Program that result from annual adaptive management review discussions are incorporated by an addendum or revision to the Integrated Comprehensive Monitoring Program as needed. The Integrated Comprehensive Monitoring Program will be routinely updated as the program evolves and progresses.

The Strategic Planning Process serves to guide the investment of resources to most efficiently address Integrated Comprehensive Monitoring Program objectives and intermediate scientific objectives. Navy-funded monitoring projects relating to the impact of Navy training and testing activities on protected marine species are designed to accomplish one or more of the following top-level goals, as described in the Integrated Comprehensive Monitoring Program charter:

- Increase the understanding of the likely occurrence of marine mammals and ESA-listed marine species in the vicinity of the action (e.g., presence, abundance, distribution, density).
- Increase the understanding of the nature, scope, or context of the likely exposure of marine mammals and ESA-listed marine species to any of the potential stressors associated with the action (e.g., acoustics, explosives, physical disturbance and strike of military expended materials) through a better understanding of one or more of the following: (1) the nature of the action and its surrounding environment (e.g., sound-source characterization, propagation,

ambient noise levels), (2) the affected species (e.g., life history, dive patterns), (3) the likely co-occurrence of marine mammals and ESA-listed marine species with the action (in whole or part), and (4) the likely biological or behavioral context of exposure to the stressor for the marine mammal and ESA-listed marine species (e.g., age class of exposed animals or known pupping, calving, or feeding areas).

- Increase the understanding of how individual marine mammals or ESA-listed marine species respond behaviorally or physiologically to the specific stressors associated with the action and in what context (e.g., at what distance or received level).
- Increase the understanding of how anticipated individual responses to individual stressors or anticipated combinations of stressors may impact either: (1) the long-term fitness and survival of an individual, or (2) the population, species, or stock (e.g., through impacts on annual rates of recruitment or survival).
- Increase the understanding of the effectiveness of mitigation and monitoring.
- Improve the understanding and record of the manner in which the Navy complies with its Incidental Take Authorizations and Incidental Take Statements.
- Increase the probability of detecting marine mammals through improved technology or methods within mitigation zones to improve mitigation effectiveness and better achieve monitoring goals.

The Navy established a Scientific Advisory Group in 2011 with the initial task of evaluating current Navy monitoring approaches under the Integrated Comprehensive Monitoring Plan and existing MMPA Regulations and Letters of Authorization. The Scientific Advisory Group was also tasked with developing objective scientific recommendations that would form the basis for the Strategic Plan. While recommendations were fairly broad and not specifically prescriptive, the Scientific Advisory Group did provide specific programmatic recommendations that serve as guiding principles for the continued evolution of the Integrated Comprehensive Monitoring Program. Key recommendations included:

- Working within a conceptual framework of knowledge, from basic information on the occurrence of species within each range complex, to more specific matters of exposure, response, and consequences.
- Facilitating collaboration among researchers in each region, with the intent to develop a coherent and synergistic regional monitoring and research effort.
- Striving to move away from effort-based compliance metrics (e.g., completing a pre-determined amount of survey hours or days), with the intent to design and conduct monitoring projects according to scientific objectives rather than effort expended.
- Approaching the monitoring program holistically and selecting projects that offer the best opportunity to advance understanding of the issues, as opposed to establishing range-specific requirements.

5.1.2.2.1.3 Strategic Planning Process

The U.S. Navy's Marine Species Monitoring Program has evolved and improved as a result of adaptive management review and the Strategic Planning Process through changes that include:

- Recognizing the limitations of effort-based compliance metrics;

- Developing a strategic approach to monitoring based on recommendations from the Scientific Advisory Group;
- Shifting focus to projects based on scientific objectives that facilitate generation of statistically meaningful results upon which natural resources management decisions may be based;
- Focusing on priority species or areas of interest as well as best opportunities to address specific monitoring objectives to maximize return on investment; and
- Increasing transparency of the program and management standards, improving collaboration among participating researchers, and improving accessibility to monitoring data and results.

As a result of the changes outlined above due to the implementation of the Strategic Planning Process, the U.S. Navy's Marine Species Monitoring Program has undergone a transition. Intermediate scientific objectives now serve as the basis for developing and executing new monitoring projects across Navy training and testing areas in the Atlantic and Pacific Oceans. Implementation of the Strategic Planning Process involves coordination among fleets, system commands, Chief of Naval Operations Energy and Environmental Readiness Division, NMFS, and the Marine Mammal Commission with five primary steps:

- **Identify overarching intermediate scientific objectives.** Through the adaptive management process, the Navy coordinates with NMFS and the Marine Mammal Commission to review and revise the list of intermediate scientific objectives that guide development of individual monitoring projects. Examples include addressing information gaps in species occurrence and density, evaluating behavioral responses of marine mammals to Navy training and testing activities, and developing tools and techniques for passive acoustic monitoring.
- **Develop individual monitoring project concepts.** This step generally takes the form of soliciting input from the scientific community in terms of potential monitoring projects that address one or more of the intermediate scientific objectives. This can be accomplished through a variety of forums, including professional societies, regional scientific advisory groups, and contractor support.
- **Evaluate, prioritize, and select monitoring projects.** Navy technical experts and program managers review and evaluate monitoring project concepts and develop a prioritized ranking. The goal of this step is to establish a suite of monitoring projects that address a cross-section of intermediate scientific objectives spread over a variety of range complexes.
- **Execute and manage selected monitoring projects.** Individual projects are initiated through appropriate funding mechanisms and include clearly defined objectives and deliverables, such as data, reports, or publications.
- **Report and evaluate progress and results.** Progress on individual monitoring projects is updated through the U.S. Navy's Marine Species Monitoring Program webpage as well as annual monitoring reports submitted to NMFS. Both internal review and discussions with NMFS through the adaptive management process are used to evaluate progress toward addressing the primary objectives of the Integrated Comprehensive Monitoring Program and serve to periodically recalibrate the focus of the monitoring program.

These steps serve three primary purposes: (1) to facilitate the Navy in developing specific projects addressing one or more intermediate scientific objectives, (2) to establish a more structured and collaborative framework for developing, evaluating, and selecting monitoring projects across areas where the Navy conducts training and testing activities, and (3) to maximize the opportunity for input

and involvement across the research community, academia, and industry. This process is designed to integrate various elements, including:

- Integrated Comprehensive Monitoring Program top-level goals,
- Scientific Advisory Group recommendations,
- Integration of regional scientific expert input,
- Ongoing adaptive management review dialog between NMFS and the Navy,
- Lessons learned from past and future monitoring of Navy training and testing, and
- Leveraging of research and lessons learned from other Navy-funded science programs.

The Strategic Planning Process will continue to shape the future of the U.S. Navy's Marine Species Monitoring Program and serve as the primary decision-making tool for guiding investments. Information on monitoring projects currently underway in the Atlantic and Pacific oceans, as well as results, reports, and publications, can be accessed through the U.S. Navy's Marine Species Monitoring Program webpage.

5.1.2.2.2 Training and Testing Activity Reports

The Navy developed a classified data repository known as the Sonar Positional Reporting System to maintain an internal record of underwater sound sources (e.g., active sonar) used during training and testing. The Sonar Positional Reporting System facilitates reporting pursuant to the Navy's MMPA Regulations and Letters of Authorization. Using data from the Sonar Positional Reporting System and other relevant sources, the Navy will continue to provide the NMFS Office of Protected Resources with classified or unclassified (depending on the data) annual reports on the training and testing activities that use underwater sound sources. In its annual training and testing activity reports, the Navy will describe the level of training and testing conducted during the reporting period. For major training exercises, the reports will also include information on each individual marine mammal sighting related to mitigation implementation. Unclassified annual training and testing activity reports that have been submitted to NMFS can be found on the NMFS Office of Protected Resources and U.S. Navy's Marine Species Monitoring Program webpages.

5.1.2.2.3 Incident Reports

The Navy's mitigation measures and many of its standard operating procedures are designed to prevent incidents involving biological and cultural resources, such as aircraft strikes, vessel strikes, and impacts on submerged historic properties and seafloor resources. The Navy has been collecting data on such incidents (if they have occurred) for more than a decade and will continue doing so under the Proposed Action. To provide information on incidents involving biological or cultural resources, the Navy will submit reports to the appropriate management authorities as described below:

- **Bird and Bat Aircraft Strikes:** As described in Section 5.1.2 (Aircraft Safety) of the 2015 MITT Final EIS/OEIS, animal strikes present an aviation safety risk for aircrews and aircraft. The Navy will report all bird and bat strikes per standard operating procedures.
- **Incidents Involving Marine Mammals, Sea Turtles, and ESA-Listed Fish:** The Navy will notify the appropriate regulatory agency (e.g., NMFS) immediately or as soon as operational security considerations allow if it observes the following that is (or may be) attributable to Navy activities: (1) a vessel strike of a marine mammal or sea turtle during training or testing, (2) a stranded, injured, or dead marine mammal or sea turtle during training or testing, or (3) an

injured or dead marine mammal, sea turtle, or ESA-listed fish species during post-explosive event monitoring. The Navy will provide relevant information pertaining to the incident (e.g., vessel speed). Additional details on these incident reporting requirements will be included in the Notification and Reporting Plan, which will be publicly available on the NMFS Office of Protected Resources webpage. The Navy will continue to provide the appropriate personnel with training on marine species incidents and their associated reporting requirements to aid the data collection and reporting processes (see Section 5.3.1, Environmental Awareness and Education). Information on marine mammal strandings is included in the *Marine Mammal Strandings Associated with U.S. Navy Sonar Activities* technical report (U.S. Department of the Navy, 2017a).

- **Corals:** The Navy will submit reports to NMFS regarding surveys of coral reef habitat and ordnance expended at FDM (e.g., observed ricochets and misses that land in waters surrounding FDM occupied by corals, observed in-water effects to corals). Additional details on the Navy's coral reporting requirements are included in the ESA Biological Opinion.
- **Cultural Resources:** In the event the Navy impacts a historic property, it will commence consultation with the appropriate State Historic Preservation Officer in accordance with 36 Code of Federal Regulations section 800.13(b)(3).

5.2 Mitigation Development Process

The Navy, in coordination with the appropriate regulatory agencies, developed its initial suite of mitigation measures for Phase I of environmental planning (2010–2015) and subsequently revised those mitigation measures for the 2015 MITT Final EIS/OEIS in Phase II (2015–2020). For this Final SEIS/OEIS (which represents Phase III of environmental planning), the Navy worked collaboratively with the appropriate regulatory agencies to develop and refine its mitigation, which was finalized through the consultation and permitting processes. The mitigation development process involved reanalyzing existing mitigation measures implemented under the 2015 MITT Final EIS/OEIS and analyzing new mitigation recommendations received from Navy and NMFS scientists, other governmental agencies, the public, and non-governmental organizations during NEPA scoping, the Draft SEIS/OEIS public review, and the consultation and permitting processes. The Navy conducted a detailed review and assessment of each potential mitigation measure individually and then all potential mitigation measures collectively to determine if, as a whole, mitigation will effectively avoid or reduce potential impacts from the Proposed Action and will be practical to implement. The Navy operational community (i.e., leadership from the aviation, surface, subsurface, and special warfare communities; leadership from the research and acquisition community; and training and testing experts), environmental planners, and scientific experts provided input on the effectiveness and practicality of mitigation implementation. Navy Senior Leadership reviewed and approved all mitigation measures included in this Final SEIS/OEIS.

Mitigation measures that the Navy will implement under the Proposed Action are organized into three categories: procedural mitigation measures for at-sea activities, at-sea mitigation areas, and terrestrial mitigation measures for activities on FDM. The sections below provide definitions of mitigation terminology, background information pertinent to the mitigation development process, and information about the mitigation effectiveness and practicality criteria. Section 5.6 (Measures Considered but Eliminated) and Appendix I (Geographic Mitigation Assessment) contain information on measures that did not meet the appropriate balance between being both effective as well as practical to implement, and therefore will not be implemented under the Proposed Action.

5.2.1 At-Sea Procedural Mitigation Development

Procedural mitigation is mitigation that the Navy will implement whenever and wherever training or testing activities involving applicable acoustic, explosive, and physical disturbance and strike stressors take place within the at-sea portion of the Study Area. Procedural mitigation generally involves: (1) the use of one or more trained Lookouts to observe for specific biological resources within a mitigation zone, (2) requirements for Lookouts to immediately communicate sightings of specific biological resources to the appropriate watch station for information dissemination, and (3) requirements for the watch station to implement mitigation until a pre-activity commencement or during-activity recommencement condition has been met.

Procedural mitigation primarily involves Lookouts observing for marine mammals and sea turtles. For some activities, Lookouts may also be required to observe for additional biological resources, such as ESA-listed fish species or jellyfish aggregations that can be an indicator of potential sea turtle presence. While on watch, Lookouts employ visual search techniques, including a combination of naked-eye scanning and the use of hand-held binoculars or high-powered binoculars mounted on a ship deck, depending on the observation platform. After sunset and prior to sunrise, Lookouts and other Navy watch personnel employ night visual search techniques, which could include the use of night vision devices.

To consider the benefits of procedural mitigation to marine mammals and sea turtles within the MMPA and ESA impact estimates, the Navy conservatively factored mitigation effectiveness into its quantitative analysis process, as described in the technical report titled *Quantifying Acoustic Impacts on Marine Mammals and Sea Turtles: Methods and Analytical Approach for Phase III Training and Testing* (U.S. Department of the Navy, 2018a). The Navy's quantitative analysis assumes that Lookouts will not be 100 percent effective at detecting all individual marine mammals and sea turtles within the mitigation zones for each activity. This is due to the inherent limitations of observing marine species and because the likelihood of sighting individual animals is largely dependent on observation conditions (e.g., time of day, sea state, mitigation zone size, observation platform) and animal behavior (e.g., the amount of time an animal spends at the surface of the water). This is particularly true for sea turtles, small marine mammals, and marine mammals that display cryptic behaviors (e.g., surfacing to breathe with only a small portion of their body visible from the surface). Throughout Section 5.3 (At-Sea Procedural Mitigation to be Implemented), discussions about the likelihood that a Lookout would observe a marine mammal or sea turtle pertain specifically to animals that are available to be observed (i.e., on, above, or just below the water's surface). The benefits of procedural mitigation measures for species that were not included in the quantitative analysis process (e.g., fish) are discussed qualitatively.

Data inputs for assessing and developing procedural mitigation included operational data as described in Section 5.2.4 (Practicality of Implementation), the best available science discussed in Chapter 3 (Affected Environment and Environmental Consequences), published literature, data on marine mammal and sea turtle impact ranges obtained through acoustic modeling, marine species monitoring and density data, and the most recent guidance from NMFS. Background information on the data that were used to develop the ranges to effect for marine mammals and sea turtles (such as hearing threshold metrics) is provided in Section 3.4 (Marine Mammals) and Section 3.5 (Sea Turtles). Additional activity or stressor-specific details, such as the level of effect to which an at-sea procedural mitigation measure is expected to mitigate and if a measure has been modified from the 2015 MITT Final EIS/OEIS is provided throughout Section 5.3 (At-Sea Procedural Mitigation to be Implemented).

5.2.1.1 Lookouts

Lookouts perform similar duties as the standard watch personnel described in Section 5.1.1 (Vessel Safety) of the 2015 MITT Final EIS/OEIS, such as personnel on the bridge watch team and personnel stationed for man-overboard precautions. Lookouts are designated the responsibility of helping meet the Navy's mitigation requirements by visually observing mitigation zones. The number of Lookouts designated for each training or testing activity is dependent upon the number of personnel involved in the activity (i.e., manning restrictions) and the number and type of assets available (i.e., equipment and space restrictions).

Depending on the activity, a Lookout may be positioned on a ship (i.e., surface ships and surfaced submarines), on a small boat (e.g., rigid-hull inflatable boat), in an aircraft, or on a pier. Certain platforms, such as aircraft and small boats, have manning or space restrictions; therefore, the Lookout on these platforms is typically an existing member of the aircraft or boat crew who is responsible for other essential tasks (e.g., a pilot or Naval Flight Officer who is responsible for navigation). Some platforms are minimally manned and are therefore either physically unable to accommodate more than one Lookout or divert personnel from mission-essential tasks, including safe and secure operation of propulsion, weapons, and damage control systems that ensure the safety of the ship and the personnel on board. The number of Lookouts specified for each activity in Section 5.3 (At-Sea Procedural Mitigation to be Implemented) represents the maximum number of Lookouts that can be designated for those activities without requiring additional personnel or reassigning duties. The "maximum" number of Lookouts is equivalent to the required number of Lookouts; therefore, the Navy would not use fewer Lookouts than what is specified in each mitigation table. The Navy is unable to position Lookouts on unmanned surface vehicles, unmanned aerial systems, unmanned underwater vehicles, and submerged submarines, or have Lookouts observe during activities that use systems deployed from or towed by unmanned platforms.

When Lookouts are positioned in a fixed-wing aircraft or rotary-wing aircraft (i.e., helicopter), mission requirements determine the flight parameters (altitude, flight path, and speed) for that aircraft. For example, most fixed-wing aircraft sorties occur above 3,000 feet (ft.), while most rotary-wing sorties associated with mine countermeasure activities occur at altitudes as low as 75–100 ft. Similarly, when Lookouts are positioned on a vessel, mission requirements determine the operational parameters (course and speed) for that vessel.

The Navy's passive acoustic devices (e.g., remote acoustic sensors, expendable sonobuoys, passive acoustic sensors on submarines) can complement visual observations for marine mammals when passive acoustic assets are already participating in an activity. The passive acoustic devices can detect vocalizing marine mammals within the frequency bands already being monitored by Navy personnel. Marine mammal detections from passive acoustic devices can alert Lookouts to possible marine mammal presence in the vicinity. Lookouts can use the information from passive acoustic detections to assist their visual observations of the mitigation zone. Based on the number and type of passive acoustic devices that are typically used, passive acoustic detections do not provide range or bearing to a detected animal in order to determine its location or confirm its presence in a mitigation zone. Therefore, it is not practical for the Navy to implement mitigation in response to passive acoustic detections alone (i.e., without a visual sighting of an animal within the mitigation zone). Additional information about passive acoustic devices is provided in Section 5.6.3 (Active and Passive Acoustic Monitoring Devices).

5.2.1.2 Mitigation Zones

Mitigation zones are areas at the surface of the water within which applicable training or testing activities will be ceased, powered down, or modified to protect specific biological resources from an auditory injury (permanent threshold shift [PTS]), non-auditory injury (from impulsive sources), or direct strike (e.g., vessel strike) to the maximum extent practicable. Mitigation zones are measured as the radius from a stressor. Implementation of procedural mitigation is most effective when mitigation zones are appropriately sized to be realistically observed during typical training and testing activity conditions.

The Navy customized its mitigation zone sizes and mitigation requirements for each applicable training and testing activity category or stressor. The Navy developed each mitigation zone to be the largest area that (1) Lookouts can reasonably be expected to observe during typical activity conditions (i.e., most environmentally protective), and (2) the Navy can commit to implementing mitigation without impacting safety, sustainability, or the ability to meet mission requirements. The Navy designed the mitigation zones for most acoustic and explosive stressors according to its source bins. As described in Section 3.0.4.1.1 (Sonar and Other Transducers), sonars and other transducers are grouped into classes that share an attribute, such as frequency range or purpose of use. Classes are further sorted by bins based on the frequency or bandwidth, source level, and when warranted, the application in which the source would be used. As described in Section 3.0.4.2.1.1 (Explosions in Water), explosives detonated in water are binned by net explosive weight. Mitigation does not pertain to stressors that do not have the potential to impact biological resources (e.g., *de minimis* acoustic and explosive sources that do not have the potential to impact marine mammals).

Discussions throughout Section 5.3 (At-Sea Procedural Mitigation to be Implemented) about the level of effect that will likely be mitigated for marine mammals and sea turtles are based on a comparison of the mitigation zone size to the predicted impact ranges for the applicable source bins with the longest average ranges to PTS. These conservative discussions represent the worst-case scenario for each activity category or stressor. The mitigation zones will oftentimes cover all or a larger portion of the predicted average ranges to PTS for other comparatively smaller sources with shorter impact ranges (e.g., sonar sources used at a lower source level, explosives in a smaller bin). The discussions are primarily focused on how the mitigation zone sizes compare to the ranges to PTS; however, depending on the activity category or stressor, the mitigation zones are oftentimes large enough to also mitigate within a portion of the ranges to temporary threshold shift (TTS). TTS is a threshold shift that is recoverable. Background information on PTS, TTS, and marine mammal and sea turtle hearing groups is presented in the U.S. Department of the Navy (2017b) technical report titled *Criteria and Thresholds for U.S. Navy Acoustic and Explosive Effects Analysis (Phase III)*.

5.2.1.3 Procedural Mitigation Implementation

The Navy takes several courses of action in response to a sighting of an applicable biological resource in a mitigation zone. First, a Lookout will communicate the sighting to the appropriate watch station. Next, the watch station will implement the prescribed mitigation, such as delaying the initial start of an activity, powering down sonar, ceasing an explosive detonation, or maneuvering a vessel. For sightings of marine mammals, sea turtles, and other specified biological resources within a mitigation zone prior to the initial start of or during applicable activities, the Navy will continue mitigating until one of the five conditions listed below has been met. The conditions are designed to allow a sighted animal to leave the mitigation zone before the initial start of an activity or before an activity resumes.

- The animal is observed exiting the mitigation zone;

- The animal is thought to have exited the mitigation zone based on a determination of its course, speed, and movement relative to the stressor source;
- The mitigation zone has been clear from any additional sightings for a specific wait period;
- For mobile activities, the stressor source has transited or has been relocated a distance equal to double that of the mitigation zone size beyond the location of the last sighting; or
- For activities using hull-mounted sonar, the ship concludes that dolphins are deliberately closing in on the ship to ride the ship's bow wave and are therefore out of the main transmission axis of the sonar (and there are no other marine mammal sightings within the mitigation zone).

To supplement the implementation of procedural mitigation, the Navy has agreed to undertake reporting initiatives for certain activities or resources based on previous consultations with NMFS, as summarized in Section 5.1.2.2 (Monitoring, Research, and Reporting Initiatives) and detailed where applicable in Section 5.3 (At-Sea Procedural Mitigation to be Implemented).

5.2.2 At-Sea Mitigation Area Development

Mitigation areas are geographic locations within the at-sea portion of the Study Area where the Navy will implement mitigation measures to (1) avoid or reduce potential impacts on biological resources located on the seafloor or submerged cultural resources; (2) in combination with procedural mitigation, to effect the least practicable adverse impact on marine mammal species or stocks and their habitat; or (3) in combination with procedural mitigation, ensure that the Proposed Action does not jeopardize the continued existence of endangered or threatened species.

The Navy completed an extensive assessment of the MITT Study Area to develop mitigation areas for the Proposed Action. The Navy reanalyzed existing mitigation areas implemented under the 2015 MITT Final EIS/OEIS and assessed habitats suggested through comments received during NEPA scoping and on the Draft SEIS/OEIS, identified by NMFS during the consultation and permitting processes, and identified internally by the Navy. Biological effectiveness and operational assessments of mitigation areas the Navy developed for marine mammals and sea turtles is provided in Appendix I (Geographic Mitigation Assessment). The appendix includes background information and additional details for each of the areas considered. Details about seafloor resource mitigation areas and summaries of the mitigation areas for marine mammals and sea turtles are presented in Section 5.4 (At-Sea Mitigation Areas to be Implemented).

Mitigation areas are designed to help avoid or reduce potential impacts in key areas of importance. Therefore, mitigation benefits are discussed qualitatively in terms of the context of impact avoidance or reduction. The Navy considers a mitigation area to be effective if it meets the following criteria:

- **The mitigation area is a key area of biological or ecological importance or contains cultural resources:** The best available science suggests that the mitigation area contains submerged cultural resources (e.g., shipwrecks) or is particularly important to one or more species or resources for a biologically important life process (e.g., foraging, migration, reproduction) or ecological function (e.g., shallow-water coral reefs that provide critical ecosystem functions); and
- **The mitigation will result in an avoidance or reduction of impacts:** Implementing the mitigation will likely avoid or reduce potential impacts on: (1) species, stocks, or populations of marine mammals based on data regarding their seasonality, density, and behavior; or (2) other biological or cultural resources based on their distribution and physical properties. Furthermore,

implementing the mitigation will not shift or transfer adverse effects from one species to another (e.g., to a more vulnerable or sensitive species).

The Navy has agreed to undertake additional reporting initiatives for the use of certain sound sources in certain mitigation areas based on consultations with NMFS under the MMPA or ESA, as summarized in Section 5.1.2.2 (Monitoring, Research, and Reporting Initiatives) and detailed where applicable in Section 5.4 (At-Sea Mitigation Areas to be Implemented).

5.2.3 Terrestrial Mitigation Measure Development

Terrestrial mitigation measures are measures that the Navy will implement during applicable military readiness activities that take place on land. FDM is the only terrestrial portion of the Study Area that the Navy plans to use under the Proposed Action. The Navy's mitigation measures on FDM primarily involve access, targeting, and ordnance restrictions, as detailed in Section 5.5 (Terrestrial Mitigation Measures to be Implemented). The terrestrial mitigation measures discussed in this Final SEIS/OEIS were originally developed for past environmental compliance documents in coordination with the U.S. Fish and Wildlife Service. Data inputs for assessing and developing terrestrial mitigation included the operational data described in Section 5.2.4 (Practicality of Implementation), the best available science discussed in Chapter 3 (Affected Environment and Environmental Consequences), published literature, and guidance from the U.S. Fish and Wildlife Service. Terrestrial mitigation measures are designed to avoid or reduce potential impacts on ESA-listed species that inhabit FDM or could occur at the island during migrations. The benefits of terrestrial mitigation measures are discussed qualitatively.

5.2.4 Practicality of Implementation

Mitigation measures are expected to have some degree of impact on the training and testing activities that implement them (e.g., modifying where and when activities occur, ceasing an activity in response to a sighting). The Navy is able to accept a certain level of impact on its military readiness activities because of the benefit that mitigation measures provide for avoiding or reducing potential impacts on environmental and cultural resources. The Navy's focus during mitigation assessment and development is that mitigation measures must meet the appropriate balance between being both effective as well as practical to implement. To evaluate practicality, the Navy operational community conducted an extensive and comprehensive assessment to determine how and to what degree potential mitigation measures would be compatible with planning, scheduling, and conducting training and testing activities under the Proposed Action in order to meet the Navy's Title 10 requirements.

5.2.4.1 Assessment Criteria

The purpose and need of the Proposed Action is to ensure that the Navy meets its mission to maintain, train, and equip combat-ready naval forces capable of winning wars, deterring aggression, and maintaining freedom of the seas. The Navy is statutorily mandated to protect U.S. national security by being ready, at all times, to effectively prosecute war and defend the nation by conducting operations at sea, as outlined in Title 10 section 8062 of the United States Code. The Navy's mission is achieved in part by conducting training and testing within the Study Area in accordance with established military readiness requirements. Training requirements have been developed through many years of iteration and adaptation and are designed to ensure that Sailors achieve the levels of readiness needed to properly respond to the multitude of contingencies they may face during military missions and combat operations. Activities are planned and scheduled in accordance with the Optimized Fleet Response Plan, which details instructions on manning distribution, range scheduling, operational requirements,

maintenance and modernization plans, quality of work and life for personnel, achieving training capabilities, and meeting strategic readiness objectives.

To achieve the highest skill proficiency and most accurate testing results possible, the Navy conducts activities in a variety of realistic tactical oceanographic and environmental conditions. Such conditions include variations in bathymetry, topography, surface fronts, and sea surface temperatures. Training activities must be as realistic as possible to provide the experiences and stressors necessary to successfully execute all required military missions and combat operations. Degraded training would result in units being unqualified to conduct the range of military operations required by operational Commanders. The inability of such Commanders to meet national security objectives would result in not only the increased risk to life, but also the degradation of national security. Testing activities must be as realistic as possible for the Navy to conduct accurate acoustic research to validate acoustic models; conduct accurate engineering tests of acoustic sources, signal processing algorithms, and acoustic interactions; and to effectively test systems and platforms (and components of these systems and platforms) to validate whether they perform as expected and determine whether they are operationally effective, suitable, survivable, and safe for their intended use by the fleet. Testing must be completed before full-scale production or delivery to the fleet to ensure functionality and accuracy in military mission and combat conditions.

As described in Chapter 2 (Description of Proposed Action and Alternatives), the Navy requires access to FDM, sea space, and airspace throughout the Study Area within pierside locations, nearshore areas, and large-scale open ocean areas of the high seas. Each area plays a critical role in the Navy's ability to plan, schedule, and effectively execute military readiness activities. The locations where training and testing occur must be situated in a way that allows the Navy to complete its activities without physical or logistical obstructions. The Navy requires extensive sea space so that individual training and testing activities can occur at sufficient distances so they do not interfere with one another. Some training and testing activities require continuous access to large and unobstructed areas, consisting potentially of tens or thousands of square miles. This provides personnel the ability to develop competence and confidence in their capabilities across multiple types of weapons and sensors, and the ability to train to communicate and operate in a coordinated fashion as required during military missions and combat operations. For example, major exercises using integrated warfare components may require large areas of the littorals, open ocean, and nearshore areas for realistic and safe anti-submarine warfare training. The Navy also requires large areas of sea space because it trains in a manner to avoid observation by potential adversaries. Modern sensing technologies make training on a large scale without observation more difficult. A foreign military's continual observation of U.S. Navy training in predictable geographic areas and timeframes would enable foreign nations to gather intelligence and subsequently develop techniques, tactics, and procedures to potentially and effectively counter U.S. naval operations. Other activities may be conducted on a smaller and more localized scale, with training or testing at discrete locations (e.g., on FDM) that are critical to certain aspects of military readiness.

The locations for training and testing activities are selected to maximize efficiency while supporting specific mission and safety requirements, deconflict sea space and airspace, and minimize the time personnel must spend away from home. Training and testing locations are typically selected based on their proximity to homeports, home bases, associated training ranges, testing facilities, air squadrons, and existing infrastructure (e.g., land ranges) to reduce travel time and associated costs. Activities involving the use of rotary-wing aircraft typically occur in proximity to shore or refueling stations due to fuel restrictions and safety requirements. Testing events are typically located near systems command

support facilities, which provide critical infrastructure support and technical expertise necessary to conduct testing. Logistical support of range testing can only efficiently and effectively occur when the support is co-located with the testing activities. These same principles also apply to pierside and at-sea testing that must occur in proximity to naval harbors. Testing event site locations and associated field activities were originally established to support specific Navy mission testing needs using a selection process that included testing requirements, cost of living, availability of personnel, and low level of crowding from industry and development.

During its assessment to determine how and to what degree the implementation of mitigation would be compatible with meeting the purpose and need of the Proposed Action, the Navy considered mitigation measures to be practical to implement if they met all criteria discussed below:

- **Implementing the mitigation is safe:** Mitigation measures must not increase safety risks to Navy personnel and equipment, or to the public. When assessing whether implementing a mitigation measure would be safe, the Navy factored in the potential for increased pilot fatigue; accelerated fatigue-life of aircraft; typical fuel restrictions of participating aircraft; locations of refueling stations; proximity to aircraft emergency landing fields, critical medical facilities, and search and rescue resources; space restrictions of the observation platforms; the ability to de-conflict platforms and activities to ensure that training and testing activities do not impact each other; and the ability to avoid interaction with non-Navy sea space and airspace uses, such as established commercial air traffic routes, commercial vessel shipping lanes, and areas used for energy exploration or alternative energy development. Other safety considerations included identifying if mitigation measures would reasonably allow Lookouts to safely and effectively maintain situational awareness while observing the mitigation zones during typical activity conditions, or if the mitigation would increase the safety risk for personnel. For example, the safety risk would increase if Lookouts were required to direct their attention away from essential mission requirements.
- **Implementing the mitigation is sustainable:** One of the primary factors that the Navy incorporates into the planning and scheduling of its training and testing activities is the amount and type of available resources, such as funding, personnel, and equipment. Mitigation measures must be sustainable over the life of the Proposed Action, meaning that they will not require the use of resources in excess of what is available. When assessing whether implementing a mitigation measure would be sustainable, the Navy considered if the measure would require excessive time on station or time away from homeport for Navy personnel, require the use of additional personnel (i.e., manpower) or equipment (e.g., adding a small boat to serve as an additional observation platform), or result in additional operational costs (e.g., increased fuel consumption, equipment maintenance, or acquisition of new equipment).
- **Implementing the mitigation allows the Navy to continue meeting its mission requirements:** The Navy considered if each individual measure and the iterative and cumulative impact of all potential measures would be within the Navy's legal authority to implement. The Navy also considered if mitigation would modify training or testing activities in a way that would prevent individual activities from meeting their mission objectives and if mitigation would prevent the Navy from meeting its national security requirements or statutorily mandated Title 10 requirements, such as by:

- Impacting training and testing realism or preventing ready access to ranges, operating areas, facilities, or range support structures (which would reduce realism and present sea space and airspace conflicts).
- Impacting the ability for Sailors to train and become proficient in using sensors and weapon systems as would be required in areas analogous to where the military operates or causing an erosion of capabilities or reduction in perishable skills (which would result in a significant risk to personnel or equipment safety during military missions and combat operations).
- Impacting the ability for units to meet their individual training and certification requirements (which would impact the ability to deploy with the required level of readiness necessary to accomplish any tasking by Combatant Commanders).
- Impacting the ability to certify forces to deploy to meet national security tasking (which would limit the flexibility of Combatant Commanders and warfighters to project power, engage in multi-national operations, and conduct the full range of naval warfighting capabilities in support of national security interests).
- Impacting the ability of researchers, program managers, and weapons system acquisition programs to conduct accurate acoustic research to meet research objectives, effectively test systems and platforms (and components of these systems and platforms) before full-scale production or delivery to the fleet, or complete shipboard maintenance, repairs, or pierside testing prior to at-sea operations (which would not allow the Navy to ensure safety, functionality, and accuracy in military mission and combat conditions per required acquisition milestones or on an as-needed basis to meet operational requirements).
- Requiring the Navy to provide advance notification of specific times and locations of Navy platforms, such as platforms using active sonar (which would present national security concerns).
- Reducing the Navy's ability to be ready, maintain deployment schedules, or respond to national emergencies or emerging national security challenges (which would present national security concerns).

5.2.4.2 Factors Affecting Practicality

Two of the factors that influenced whether procedural mitigation measures met the practicality criteria were the number of times mitigation measures would likely be implemented and the duration over which the activity would likely be ceased due to mitigation implementation. The number of times mitigation would likely be implemented is largely dependent on the size of the mitigation zone. As a mitigation zone size increases, the area of observation increases by an order of magnitude. This is because mitigation zones are measured as the radius (r) from a stressor but apply to circular area (A) around that stressor ($A = \pi * r^2$, where π is a constant that is approximately equal to 3.14). For example, a 100-yard (yd.) mitigation zone is equivalent to an area of 31,416 square yd. A 200 yd. mitigation zone is equivalent to an area of 125,664 square yd. Therefore, increasing a mitigation zone from 100 yd. to 200 yd. (i.e., doubling the mitigation zone radius) would quadruple the mitigation zone area (the area over which mitigation must be implemented). Similarly, increasing a mitigation zone from 1,000 yd. to 4,000 yd. (i.e., quadrupling the mitigation zone radius) would increase the mitigation zone area by a factor of 16. Increasing the area over which mitigation must be implemented consequently increases the number of times mitigation would likely be implemented during that activity.

The duration over which mitigation is implemented can differ considerably depending on the mitigation zone size, number of animal sightings, behavioral state of animals sighted (e.g., travelling at a fast pace on course to exit the mitigation zone, milling slowly in the center of the mitigation zone), and which pre-activity commencement or during-activity recommencement condition is met before the activity can commence or resume after each sighting. The duration of mitigation implementation typically equates to the amount of time the training or testing activity will be extended. The impact that extending the length of an activity has on safety, sustainability, and the Navy's ability to accomplish the activity's intended objectives varies by activity. This is one reason why the Navy tailors its mitigation zone sizes and mitigation requirements by activity category or stressor and the platforms involved.

As described in Section 5.2.1 (At-Sea Procedural Mitigation Development), the Navy will mitigate for each applicable sighting and will continue mitigating until one of five conditions has been met. In some instances, such as if an animal dives underwater after a sighting, it may not be possible for a Lookout to visually verify if the animal has exited the mitigation zone. The Navy cannot delay or cease activities indefinitely for the purpose of mitigation due to impacts on safety, sustainability, and the Navy's ability to continue meeting its mission requirements. To account for this, one of the pre-activity commencement and during-activity recommencement conditions is an established post-sighting wait period of 30 minutes or 10 minutes, based on the platforms involved. Wait periods are designed to allow animals the maximum amount of time practical to resurface (i.e., become available to be observed by a Lookout) before activities resume. When developing the length of its wait periods, the Navy factored in the assumption that mitigation may need to be implemented more than once. For example, an activity may need to be delayed or ceased for more than one 30-minute or 10-minute period.

The Navy assigns a 30-minute wait period to activities conducted from vessels and that involve aircraft that are not typically fuel constrained (e.g., maritime patrol aircraft). A 30-minute period covers the average dive times of most marine mammals and a portion of the dive times of sea turtles and deep-diving marine mammals (i.e., sperm whales, dwarf and pygmy sperm whales [Kogia whales], and beaked whales) (U.S. Department of the Navy, 2017c). The Navy determined that a 30-minute wait period is the maximum wait time that is practical to implement during activities involving vessels and aircraft that are not typically fuel constrained to allow the activities to continue meeting their intended objectives. For example, the typical duration of Maritime Security Operations – Anti-Swimmer Grenades (which involve the use of small boats) is one hour. These activities are scheduled to occur at specific locations within specific timeframes based on range scheduling and for sea space deconfliction. Implementing one wait period would result in the activity being extended by half of the typical activity duration. The Navy determined that, given the benefit of this mitigation, a 30-minute wait period would be practical to implement for this activity; however, implementing a longer wait period (such as extending the wait period to 45 or 60 minutes to cover the average dive times of sea turtles and additional marine mammal species) would be impractical. Increasing the wait period, and consequently, the amount of time the activity would need to be delayed or extended in order to accomplish its intended objective, would impact activity realism or cause sea space conflicts in a way that could impact the Navy's ability to continue meeting its mission requirements. For example, delaying an activity for multiple wait periods could result in personnel not being able to detonate an explosive before the participating platforms are required to depart the range due to range scheduling; therefore, the activity would not accomplish its intended objectives.

The Navy assigns a 10-minute wait period to activities involving aircraft that are typically fuel constrained (e.g., rotary-wing aircraft, fighter aircraft). A 10-minute period covers a portion, but not the

average, dive times of marine mammals and sea turtles (U.S. Department of the Navy, 2017c). The Navy determined that a 10-minute wait period is the maximum wait time that is practical to implement during activities involving aircraft that are typically fuel constrained. Increasing the wait period, and consequently the amount of time the training or testing activity would need to be extended in order to accomplish its intended objective, would require aircraft to depart the activity area to refuel in order to safely complete the event. If the wait period was implemented multiple times, the aircraft would be required to depart the activity area to refuel multiple times. Refueling events would vary in duration, depending on the activity location and proximity to the nearest refueling station. Multiple refueling events would generally be expected to extend the length of the activity by two to five times or more. This would impact activity realism, could cause air space or sea space conflicts in a way that could impact the Navy's ability to continue meeting its mission requirements, would decrease the ability for Lookouts to safely and effectively maintain situational awareness of the activity area, and would increase safety risks due to increased pilot fatigue and accelerated fatigue-life of aircraft. For example, delaying a Torpedo Exercise – Helicopter activity for multiple wait periods could result in personnel not being able to effectively search for, detect, classify, localize, and track a simulated threat submarine before the rotary-wing aircraft is required to depart the range due to range scheduling; therefore, the activity would not accomplish its intended objectives.

Factors that influenced whether a mitigation area measure met the practicality criteria included the historical use and projected future use of geographic locations for training and testing activities under the Proposed Action, and the relative importance of each location. The frequency that an area is used for training or testing does not necessarily equate to that area's level of importance for meeting an individual activity objective, or collectively, the Navy's mission requirements. While frequently used areas can be essential to one or more types of military readiness activities, some infrequently used areas are critical for a particular training exercise, testing mission, or research project.

5.3 At-Sea Procedural Mitigation to be Implemented

The first at-sea procedural mitigation measure (Section 5.3.1, Environmental Awareness and Education) is designed to aid Lookouts and other personnel with observation, environmental compliance, and reporting responsibilities. The remaining procedural mitigation measures are organized by stressor type and training or testing activity category.

5.3.1 Environmental Awareness and Education

The Navy will continue to implement procedural mitigation to provide environmental awareness and education to the appropriate personnel to aid visual observation, environmental compliance, and reporting responsibilities, as outlined in Table 5-1.

Table 5-1: Environmental Awareness and Education

Procedural Mitigation Description
Stressor or Activity • All training and testing activities, as applicable
Resource Protection Focus • Marine mammals • Sea turtles
Mitigation Requirements • Appropriate personnel (including civilian personnel) involved in mitigation and training or testing activity reporting under the Proposed Action will complete one or more modules of the U.S. Navy Afloat Environmental Compliance Training Series, as identified in their career path training plan. Modules include: – **Introduction to the U.S. Navy Afloat Environmental Compliance Training Series.** The introductory module provides information on environmental laws (e.g., ESA, MMPA) and the corresponding responsibilities that are relevant to Navy training and testing activities. The material explains why environmental compliance is important in supporting the Navy's commitment to environmental stewardship. – **Marine Species Awareness Training.** All bridge watch personnel, Commanding Officers, Executive Officers, maritime patrol aircraft aircrews, anti-submarine warfare and mine warfare rotary-wing aircrews, Lookouts, and equivalent civilian personnel must successfully complete the Marine Species Awareness Training prior to standing watch or serving as a Lookout. The Marine Species Awareness Training provides information on sighting cues, visual observation tools and techniques, and sighting notification procedures. Navy biologists developed Marine Species Awareness Training to improve the effectiveness of visual observations for biological resources, focusing on marine mammals and sea turtles, and including jellyfish aggregations and flocks of seabirds. – **U.S. Navy Protective Measures Assessment Protocol.** This module provides the necessary instruction for accessing mitigation requirements during the event planning phase using the Protective Measures Assessment Protocol software tool. – **U.S. Navy Sonar Positional Reporting System and Marine Mammal Incident Reporting.** This module provides instruction on the procedures and activity reporting requirements for the Sonar Positional Reporting System and marine mammal incident reporting.

The Navy requires Lookouts and other personnel to complete their assigned environmental compliance responsibilities (e.g., mitigation, reporting requirements) before, during, and after training and testing activities. Marine Species Awareness Training was first developed in 2007 and has since undergone numerous updates to ensure that the content remains current, with the most recent product approved by NMFS and released by the Navy in 2014. In 2014, the Navy developed a series of educational training modules, known as the Afloat Environmental Compliance Training program, to ensure Navywide compliance with environmental requirements. The Afloat Environmental Compliance Training program, including the updated Marine Species Awareness Training, helps Navy personnel from the most junior Sailors to Commanding Officers gain a better understanding of their personal environmental compliance roles and responsibilities. Additional information on the Protective Measures Assessment Protocol is provided in Section 5.1.2.1 (Protective Measures Assessment Protocol), and additional information on training and testing activity and incident reports is provided in Section 5.1.2.2 (Monitoring, Research, and Reporting Initiatives).

From an operational perspective, the interactive web-based format of the U.S. Navy Afloat Environmental Compliance Training Series is ideal for providing engaging and educational content that is cost effective and convenient to access by personnel who oftentimes face rotating job assignments. The U.S. Navy Afloat Environmental Compliance Training Series has resulted in an improvement in the quality and accuracy of training and testing activity reports, incident reports, and Sonar Positional Reporting System reports submitted by Navy operators. Improved reporting quality indicates that the U.S. Navy Afloat Environmental Compliance Training Series is helping to facilitate Navywide environmental compliance as intended.

Lookouts and members of the operational community have demonstrated enhanced knowledge and understanding of the Navy's environmental compliance responsibilities since the development of the U.S. Navy Afloat Environmental Compliance Training Series. To date, the Navy has had zero vessel strikes of marine mammals in the Study Area. Outside of the Study Area, there has been a decrease in Navy vessel strikes of marine mammals since implementation of the Marine Species Awareness Training in 2007. It is likely that the implementation of the Marine Species Awareness Training starting in 2007, and the additional U.S. Navy Afloat Environmental Compliance Training Series modules starting in 2014, potentially helped contribute to the lack of vessel strikes of marine mammals in the Study Area and decrease in vessel strikes of marine mammals outside of the Study Area. This indicates that the environmental awareness and education program is helping to improve the effectiveness of mitigation implementation. A more detailed analysis of vessel strikes is presented in Section 3.4.2.4 (Physical Disturbance and Strike Stressors) of this Final SEIS/OEIS.

5.3.2 Acoustic Stressors

The Navy will implement procedural mitigation to avoid or reduce potential impacts on biological resources at sea from the acoustic stressors or activities discussed in the sections below.

5.3.2.1 Active Sonar

The Navy will continue to implement procedural mitigation to avoid or reduce potential impacts on marine mammals and sea turtles from active sonar, as outlined in Table 5-2. In addition to procedural mitigation, the Navy will implement mitigation for active sonar within mitigation areas. Mitigation area requirements for active sonar are detailed in Appendix I (Geographic Mitigation Assessment).

In the 2015 MITT Final EIS/OEIS, the Navy's active sonar mitigation zones were based on associated average ranges to PTS. When developing the mitigation for this Final SEIS/OEIS, the Navy analyzed the potential for increasing the sizes of these mitigation zones. The Navy determined that the current mitigation zones for active sonar are the largest areas within which it is practical to implement mitigation; therefore, it will continue implementing these same mitigation zones under the Proposed Action.

The Navy is clarifying in the table that the mitigation zone for low-frequency active sonar sources at or above 200 dB will be the same as the mitigation implemented for hull-mounted mid-frequency active sonar; whereas low-frequency active sonar sources below 200 dB will implement the same mitigation zone as high-frequency active sonar and mid-frequency active sonar sources that are not hull-mounted. The Navy is also clarifying that it will require observation of the mitigation zone prior to the initial start of the activity to ensure the area is clear of applicable biological resources. The Navy has always verified that the mitigation zone is visually clear prior to conducting active sonar activities and is more clearly capturing this current practice in the mitigation measures for this activity. The Navy will follow the incident reporting procedures outlined in Section 5.1.2.2.3 (Incident Reports) if an incident is detected at any time during the event. The mitigation zone sizes and proximity to the observation platforms will result in a high likelihood that Lookouts will be able to detect marine mammals and sea turtles throughout the mitigation zones.

Table 5-2: Procedural Mitigation for Active Sonar

Procedural Mitigation Description
Stressor or Activity • Low-frequency active sonar, mid-frequency active sonar, high-frequency active sonar – For vessel-based active sonar activities, mitigation applies only to sources that are positively controlled and deployed from manned surface vessels (e.g., sonar sources towed from manned surface platforms). – For aircraft-based active sonar activities, mitigation applies only to sources that are positively controlled and deployed from manned aircraft that do not operate at high altitudes (e.g., rotary-wing aircraft). Mitigation does not apply to active sonar sources deployed from unmanned aerial systems or aircraft operating at high altitudes (e.g., maritime patrol aircraft).
Resource Protection Focus • Marine mammals • Sea turtles (only for sources <2 kilohertz [kHz])
Number of Lookouts and Observation Platform • Hull-mounted sources: – 1 Lookout: Platforms with space or manning restrictions while underway (at the forward part of a small boat or ship) and platforms using active sonar while moored or at anchor (including pierside) – 2 Lookouts: Platforms without space or manning restrictions while underway (at the forward part of the ship) • Sources that are not hull-mounted: – 1 Lookout on the ship or aircraft conducting the activity
Mitigation Requirements • Mitigation zones: – 1,000 yd. power down, 500 yd. power down, and 200 yd. shut down for low-frequency active sonar ≥200 decibels (dB) and hull-mounted mid-frequency active sonar – 200 yd. shut down for low-frequency active sonar <200 dB, mid-frequency active sonar sources that are not hull-mounted, and high-frequency active sonar • Prior to the initial start of the activity (e.g., when maneuvering on station): – Observe the mitigation zone for marine mammals and sea turtles; if observed, relocate or delay the start of active sonar transmission. • During the activity: – Low-frequency active sonar ≥200 decibels (dB) and hull-mounted mid-frequency active sonar: Observe the mitigation zone for marine mammals and sea turtles (for sources <2 kHz); power down active sonar transmission by 6 dB if observed within 1,000 yd. of the sonar source; power down an additional 4 dB (10 dB total) within 500 yd.; cease transmission within 200 yd. – Low-frequency active sonar <200 dB, mid-frequency active sonar sources that are not hull-mounted, and high-frequency active sonar: Observe the mitigation zone for marine mammals and sea turtles (for sources <2 kHz); cease active sonar transmission if observed within 200 yd. of the sonar source. • Commencement/recommencement conditions after a marine mammal or sea turtle sighting before or during the activity: – The Navy will allow a sighted marine mammal or sea turtle to leave the mitigation zone prior to the initial start of the activity (by delaying the start) or during the activity (by not recommencing or powering up active sonar transmission) until one of the following conditions has been met: (1) the animal is observed exiting the mitigation zone; (2) the animal is thought to have exited the mitigation zone based on a determination of its course, speed, and movement relative to the sonar source; (3) the mitigation zone has been clear from any additional sightings for 10 minutes for aircraft-deployed sonar sources or 30 minutes for vessel-deployed sonar sources; (4) for mobile activities, the active sonar source has transited a distance equal to double that of the mitigation zone size beyond the location of the last sighting; or (5) for activities using hull-mounted sonar, the ship concludes that dolphins are deliberately closing in on the ship to ride the ship's bow wave, and are therefore out of the main transmission axis of the sonar (and there are no other marine mammal sightings within the mitigation zone).

Section 3.4.2.1.2 (Impacts from Sonar and Other Transducer Stressors) of this Final SEIS/OEIS provides a full analysis of the potential impacts of sonar on marine mammals and includes the impact ranges for various source bins. For low-frequency active sonar at 200 dB or more and hull-mounted mid-frequency active sonar, bin MF1 has the longest predicted ranges to PTS. For low-frequency active sonar below 200 dB, mid-frequency active sonar sources that are not hull-mounted, and high-frequency active sonar, bin HF4 has the longest predicted ranges to PTS. For the highest source levels in bin MF1 and HF4, the mitigation zones extend beyond the respective average ranges to PTS for marine mammals. The

mitigation zones for active sonar will help avoid or reduce the potential for exposure to PTS for marine mammals.

The active sonar mitigation zones also extend into a portion of the average ranges to TTS for marine mammals; therefore, mitigation will help avoid or reduce the potential for some exposure to higher levels of TTS. Active sonar sources that fall within lower source bins or are used at lower source levels have shorter impact ranges than those discussed above; therefore, the mitigation zones will extend further beyond or into the average ranges to PTS and TTS for these sources. The analysis in Section 3.4.2.1.2 (Impacts from Sonar and Other Transducers) of this Final SEIS/OEIS indicates that pygmy and dwarf sperm whales (Kogia whales) are the only deep-diving marine mammal species that could potentially experience PTS impacts from active sonar in the Study Area. The 30-minute wait period for vessel-deployed sources will cover the average dive times of marine mammal species that could experience PTS from sonar in the mitigation zone, except for Kogia whales. The 10-minute wait period for aircraft-deployed sources will cover a portion, but not the average, dive times of marine mammals.

Section 3.5.2.1.2 (Impacts from Sonar and Other Transducers) provides a full analysis of the potential impacts of sonar on sea turtles. Due to sea turtle hearing capabilities, the mitigation only applies to sea turtles during the use of sources below 2 kilohertz. The range to auditory effects for most active sonar sources in sea turtle hearing range (e.g., LF4) is zero meters. Impact ranges are longer (i.e., up to tens of meters) for active sonars with higher source levels. The mitigation zones for active sonar extend beyond the ranges to PTS and TTS for sea turtles; therefore, mitigation will help avoid or reduce the potential for exposure to these effects for sea turtles.

The Navy currently uses, and will continue to use, computer simulation to augment training and testing whenever possible. As discussed in Section 1.4.1 (Why the Navy Trains), simulators and synthetic training are critical elements that provide early skill repetition and enhance teamwork; however, they cannot replicate the complexity and stresses faced by Sailors during military missions and combat operations to which the Navy trains under the Proposed Action (e.g., anti-submarine warfare training using hull-mounted mid-frequency active sonar). As described previously, the mitigation zones developed for this Final SEIS/OEIS are based on the largest areas within which it is practical for the Navy to implement mitigation during training and testing within the Study Area. Training and testing with active sonar are essential to national security. Active sonar is the only reliable technology for detecting and tracking potential enemy diesel-electric submarines. For example, small diesel-electric submarines operate quietly and may hide in shallow coastal and littoral waters. The ability to effectively operate active sonar is a highly perishable skill that must be repeatedly practiced during realistic training. Naval forces must train in the same mode and manner in which they conduct military missions and combat operations. Anti-submarine warfare training typically involves the periodic use of active sonar to develop the “tactical picture,” or an understanding of the battle space (e.g., area searched or unsearched, identifying false contacts, and understanding the water conditions). This can take from several hours to multiple days and typically occurs over vast areas with varying physical and oceanographic conditions (e.g., bathymetry, topography, surface fronts, and variations in sea surface temperature). Sonar operators train to avoid or reduce interference and sound-reducing clutter from varying ocean floor topographies and environmental conditions, practice coordinating their efforts with other sonar operators in a strike group, develop skill proficiency in detecting and tracking submarines and other threats, and practice the focused endurance vital to effectively working as a team in shifts around the clock until the conclusion of the event.

Increasing the mitigation zone sizes would result in a larger area over which active sonar would need to be powered down or shut down in response to a sighting, and therefore would likely increase the number of times that these mitigation measures would be implemented. This would extend the length of the activity, significantly diminish event realism, and prevent activities from meeting their intended objectives. It would also create fundamental differences between how active sonar would be used in training and how active sonar should be used during military missions and combat operations. For example, additional active sonar power downs or shut downs would prevent sonar operators from developing and maintaining awareness of the tactical picture during training events. Without realistic training in conditions analogous to military missions and combat operations, sonar operators cannot become proficient in effectively operating active sonar. Sonar operators, vessel crews, and aircrews would be expected to operate active sonar during military missions and combat operations in a manner inconsistent with how they were trained.

During integrated training, multiple vessels and aircraft may participate in an exercise using different warfare components simultaneously. Degrading the value of one training element results in a degradation of the training value of the other training elements. Degrading the value of training would cause a reduction in perishable skills and diminished operational capability, which would significantly impact military readiness. Each of these factors would ultimately impact the ability for units to meet their individual training and certification requirements and the Navy's ability to certify forces to safely deploy to meet national security tasking. Diminishing proficiency or eroding active sonar capabilities would present a significant risk to personnel safety during military missions and combat operations and would impact the ability to deploy with the required level of readiness necessary to accomplish any tasking by Combatant Commanders.

Increasing the number of times that the Navy must power down or shut down active sonar transmissions during testing activities would result in similar consequences to activity realism. For example, at-sea sonar testing activities are required in order to calibrate or document the functionality of sonar and torpedo systems while a ship or submarine is in an open ocean environment. Additional powering down or shutting down active sonar transmissions would prevent this activity from meeting its intended objective, such as verifying if the ship meets design acoustic specifications. These types of impacts would impede the ability of researchers, program managers, and weapons system acquisition programs to meet research objectives and testing requirements per required acquisition milestones or on an as-needed basis to meet operational requirements, and would impede shipboard maintenance, repairs, or pierside testing prior to at-sea operations.

For activities that involve aircraft (e.g., activities involving rotary-wing aircraft that use dipping sonar or sonobuoys to locate submarines or submarine targets), extending the length of the activity would require aircraft to depart the area to refuel. If multiple refueling events were required, the length of the activity would be extended by two to five times or more, which would decrease the ability for Lookouts to safely and effectively maintain situational awareness of the activity area and increase safety risks due to increased pilot fatigue and accelerated fatigue-life of aircraft. Extending the length of the activity would also result in additional operational costs due to increased fuel consumption. Increasing the mitigation zone sizes would not result in a substantial reduction of injurious impacts because, as described above, the mitigation zones extend beyond the average ranges to PTS for sea turtles and marine mammals.

In summary, the operational community determined that implementing procedural mitigation for active sonar beyond what is detailed in Table 5-2 would be incompatible with the practicality assessment criteria for safety, sustainability, and mission requirements.

5.3.2.2 Weapons Firing Noise

The Navy will continue to implement procedural mitigation to avoid or reduce potential impacts on marine mammals and sea turtles from weapons firing noise, as outlined in Table 5-3.

Table 5-3: Procedural Mitigation for Weapons Firing Noise

Procedural Mitigation Description
Stressor or Activity • Weapons firing noise associated with large-caliber gunnery activities
Resource Protection Focus • Marine mammals • Sea turtles
Number of Lookouts and Observation Platform • 1 Lookout positioned on the ship conducting the firing – Depending on the activity, the Lookout could be the same one described in Section 5.3.3.3 (Explosive Medium-Caliber and Large-Caliber Projectiles) or Section 5.3.4.3 (Small-, Medium-, and Large-Caliber Non-Explosive Practice Munitions).
Mitigation Requirements • Mitigation zone: – 30° on either side of the firing line out to 70 yd. from the muzzle of the weapon being fired • Prior to the initial start of the activity: – Observe the mitigation zone for marine mammals and sea turtles; if observed, relocate or delay the start of weapons firing. • During the activity: – Observe the mitigation zone for marine mammals and sea turtles; if observed, cease weapons firing. • Commencement/recommencement conditions after a marine mammal or sea turtle sighting before or during the activity: – The Navy will allow a sighted marine mammal or sea turtle to leave the mitigation zone prior to the initial start of the activity (by delaying the start) or during the activity (by not recommencing weapons firing) until one of the following conditions has been met: (1) the animal is observed exiting the mitigation zone; (2) the animal is thought to have exited the mitigation zone based on a determination of its course, speed, and movement relative to the firing ship; (3) the mitigation zone has been clear from any additional sightings for 30 minutes; or (4) for mobile activities, the firing ship has transited a distance equal to double that of the mitigation zone size beyond the location of the last sighting.

In the 2015 MITT Final EIS/OEIS, the weapons firing noise mitigation zone was based on the associated average ranges to PTS. When developing the mitigation for this Final SEIS/OEIS, the Navy analyzed the potential for increasing the size of the mitigation zone. The Navy determined that the current mitigation zone is the largest area within which it is practical to implement mitigation for this activity; therefore, it will continue implementing the same mitigation zone size under the Proposed Action. The Navy is clarifying in the table that it will require observation of the mitigation zone prior to the initial start of the activity to ensure the area is clear of applicable biological resources. The Navy has always verified that the mitigation zone is visually clear prior to conducting weapons firing activities and is more clearly capturing this current practice in the mitigation measures for this activity. The Navy will follow the incident reporting procedures outlined in Section 5.1.2.2.3 (Incident Reports) if an incident is detected at any time during the event.

Section 3.4.4.2.5 (Impacts from Weapons Firing, Launch, and Impact Noise) and Section 3.5.3.1.8 (Impacts from Weapons Firing, Launch, and Impact Noise) of the 2015 MITT Final EIS/OEIS provide a full analysis of the potential impacts of weapons noise on marine mammals and sea turtles, respectively. As described in Section 3.0.5.2.1.4 (Weapons Firing, Launch, and Impact Noise) of the 2015 MITT Final EIS/OEIS, underwater sounds from large-caliber weapons firing activities would be strongest just below

the surface and directly under the firing point. Any sound that enters the water only does so within a narrow cone below the firing point or path of the projectile. The mitigation zone extends beyond the distance to which marine mammals and sea turtles would likely experience PTS or TTS from weapons firing noise; therefore, mitigation will help avoid or reduce the potential for exposure to these impacts. The small mitigation zone size and proximity to the observation platform will result in a high likelihood that Lookouts will be able to detect marine mammals and sea turtles throughout the mitigation zone.

As described previously, the mitigation zone developed for this Final SEIS/OEIS is based on the largest area within which it is practical for the Navy to implement mitigation for this activity. Increasing the mitigation zone would result in a larger area over which weapons firing would need to be ceased in response to a sighting, and therefore would likely increase the number of times weapons firing would be ceased. However, increasing the mitigation zone size would not result in a substantial reduction of injurious impacts because the mitigation zone extends beyond the average ranges to PTS for sea turtles and marine mammals.

Large-caliber gunnery training activities may involve a single ship firing or may be conducted as part of a larger exercise involving multiple ships. Surface ship crews learn to track targets (e.g., with radar), engage targets, practice defensive marksmanship, and coordinate their efforts within the context of larger activities. Increasing the number of times that the Navy must cease weapons firing during training would decrease realism and impact the ability for Navy Sailors to train and become proficient in using large-caliber guns as required during military missions and combat operations. For example, additional ceasing of the activity would reduce the crew's ability to react to changes in the tactical situation or respond to an incoming threat, which could result in a delay to the ship's training schedule. When training is undertaken in the context of a coordinated exercise involving multiple ships, degrading the value of one of the training elements results in a degradation of the training value of the other training elements. These factors would ultimately impact the ability for units to meet their individual training and certification requirements, and the Navy's ability to certify forces to deploy to meet national security tasking.

In summary, the operational community determined that implementing procedural mitigation for weapons firing noise beyond what is detailed in Table 5-3 would be incompatible with the practicality assessment criteria for safety and mission requirements.

5.3.3 Explosive Stressors

The Navy will implement procedural mitigation to avoid or reduce potential impacts on biological resources at sea from the explosives discussed in the sections below. Section 3.4.2.2 (Explosive Stressors) and Section 3.5.2.2 (Explosive Stressors) provide a full analysis of potential impacts of explosives on marine mammals and sea turtles, respectively, including predicted impact ranges. In addition to procedural mitigation, the Navy will implement mitigation for explosives within mitigation areas. Mitigation area requirements for explosives are detailed in Appendix I (Geographic Mitigation Assessment).

5.3.3.1 Explosive Sonobuoys

The Navy will continue to implement procedural mitigation to avoid or reduce potential impacts on marine mammals and sea turtles from explosive sonobuoys, as outlined in Table 5-4. In the 2015 MITT Final EIS/OEIS, explosive sonobuoys had two mitigation zone sizes based on net explosive weight and the associated average ranges to PTS. When developing mitigation for this Final SEIS/OEIS, the Navy analyzed the potential for increasing the size of these mitigation zones. The Navy identified an

opportunity to increase the mitigation zone size by 250 yd. for sonobuoys using up to 2.5-pound (lb.) net explosive weight so that explosive sonobuoys will implement a 600 yd. mitigation zone, regardless of net explosive weight, to enhance protections to the maximum extent practicable. This increase is reflected in Table 5-4. The mitigation zone for explosive sonobuoys is now based on the largest area within which it is practical to implement mitigation.

Table 5-4: Procedural Mitigation for Explosive Sonobuoys

Procedural Mitigation Description
Stressor or Activity • Explosive sonobuoys
Resource Protection Focus • Marine mammals • Sea turtles
Number of Lookouts and Observation Platform • 1 Lookout positioned in an aircraft or on a small boat • If additional platforms are participating in the activity, personnel positioned in those assets (e.g., safety observers, evaluators) will support observing the mitigation zone for applicable biological resources while performing their regular duties.
Mitigation Requirements • Mitigation zone: – 600 yd. around an explosive sonobuoy • Prior to the initial start of the activity (e.g., during deployment of a sonobuoy pattern, which typically lasts 20–30 minutes): – Conduct passive acoustic monitoring for marine mammals; use information from detections to assist visual observations. – Visually observe the mitigation zone for marine mammals and sea turtles; if observed, relocate or delay the start of sonobuoy or source/receiver pair detonations. • During the activity: – Observe the mitigation zone for marine mammals and sea turtles; if observed, cease sonobuoy or source/receiver pair detonations. • Commencement/recommencement conditions after a marine mammal or sea turtle sighting before or during the activity: – The Navy will allow a sighted marine mammal or sea turtle to leave the mitigation zone prior to the initial start of the activity (by delaying the start) or during the activity (by not recommencing detonations) until one of the following conditions has been met: (1) the animal is observed exiting the mitigation zone; (2) the animal is thought to have exited the mitigation zone based on a determination of its course, speed, and movement relative to the sonobuoy; or (3) the mitigation zone has been clear from any additional sightings for 10 minutes when the activity involves aircraft that have fuel constraints, or 30 minutes when the activity involves aircraft that are not typically fuel constrained. • After completion of the activity (e.g., prior to maneuvering off station): – When practical (e.g., when platforms are not constrained by fuel restrictions or mission-essential follow-on commitments), observe the vicinity of where detonations occurred; if any injured or dead marine mammals or ESA-listed species are observed, follow established incident reporting procedures. – If additional platforms are supporting this activity (e.g., providing range clearance), these assets will assist in the visual observation of the area where detonations occurred.

The Navy is clarifying in the table that it will require observation of the mitigation zone prior to the initial start of the activity to ensure the area is clear of applicable biological resources. The Navy has always verified that the mitigation zone is visually clear prior to conducting explosive activities and is more clearly capturing this current practice in the mitigation measures for this activity. The Navy developed a new mitigation measure requiring the Lookout to observe the mitigation zone after completion of the activity. In accordance with the 2015 MITT Final EIS/OEIS consultation requirements, the Navy currently conducts post-activity observations for some, but not all explosive activities. When developing mitigation for this Final SEIS/OEIS, the Navy determined that it could expand this requirement to other explosive activities for enhanced consistency and to help determine if any resources were injured during explosive events, when practical. The Navy is adding a requirement that additional platforms already participating in the activity will support observing the mitigation zone before, during, and after the

activity while performing their regular duties. There are typically multiple platforms in the vicinity of activities that use explosive sonobuoys (e.g., safety aircraft). When available, having additional personnel support observations of the mitigation zone will help increase the likelihood of detecting biological resources. The Navy will follow the incident reporting procedures outlined in Section 5.1.2.2.3 (Incident Reports) if an incident is detected at any time during the event, including during the post-activity observations.

Some activities that use explosive sonobuoys involve detonations of a single sonobuoy or sonobuoy pair, while other activities involve deployment of multiple sonobuoys that may be dispersed in a pattern over a large distance. Lookouts will have a better likelihood of detecting marine mammals and sea turtles when observing the mitigation zone around a single sonobuoy or sonobuoy pair than when observing multiple sonobuoys dispersed over a large distance. When observing large distances, Lookouts will be more likely to detect large visual cues (e.g., whale blows or large pods of dolphins) than individual marine mammals, cryptic marine mammal species, and sea turtles.

Bin E3 has the longest predicted impact ranges for explosive sonobuoys used in the Study Area (e.g., MK-61 SUS sonobuoys). For the largest explosive in bin E3, the mitigation zone extends beyond the ranges to 50 percent non-auditory injury and 50 percent mortality for sea turtles and marine mammals. The mitigation zone extends beyond the average ranges to PTS for sea turtles and mid-frequency cetaceans, and into a portion of the average ranges to PTS for high-frequency cetaceans and low-frequency cetaceans. The mitigation zone also extends beyond or into a portion of the average ranges to TTS for sea turtles and marine mammals. Therefore, depending on the species, mitigation will help avoid or reduce all or a portion of the potential for exposure to mortality, non-auditory injury, PTS, and higher levels of TTS for the largest explosives in bin E3. Smaller explosives in bin E3 and explosives in smaller source bins (E1) have shorter predicted impact ranges; therefore, the mitigation zone will extend further beyond or cover a greater portion of the impact ranges for these explosives.

As described previously, the mitigation zone developed for this Final SEIS/OEIS is based on the largest area within which it is practical for the Navy to implement mitigation. It is not practical to increase the mitigation zone because observations within the margin of increase would be ineffective unless the Navy allocated additional platforms to observe for biological resources. This is particularly true when observations occur from a small boat or during observations over a large distance. The use of additional personnel and equipment (aircraft or small boats) would be unsustainable due to increased operational costs and an exceedance of the available manpower and resources for this activity. Adding aircraft to observe the mitigation zone could result in airspace conflicts with the event participants. This would either require the aircraft conducting the activity to modify their flight plans (which would reduce activity realism) or force the observing aircraft to position itself a safe distance away from the activity area (which would decrease observation effectiveness). Adding vessels to observe the mitigation zone would increase safety risks due to the presence of observation vessels within the vicinity of an explosive sonobuoy or pattern of explosive sonobuoys.

Increasing the mitigation zone size would result in a larger area over which detonations would need to be ceased in response to a sighting, and therefore would likely increase the number of times detonations would be ceased and would extend the length of the activity. These impacts would significantly diminish event realism in a way that would prevent the activity from meeting its intended objectives. For example, during Anti-Submarine Warfare Tracking Test – Maritime Patrol Aircraft events, additional ceasing of the activity would not allow the Navy to effectively test sensors and systems that are used to detect and track submarines and ensure that systems perform to specifications and meet

operational requirements. Such testing is required to ensure functionality and accuracy in military mission and combat conditions. Extending the length of the activity would require aircraft to depart the area to refuel. If multiple refueling events were required, the activity length would extend by two to five times or more, which would decrease the ability for Lookouts to safely and effectively maintain situational awareness of the activity area and increase safety risks due to increased pilot fatigue and accelerated fatigue-life of aircraft. Extending the length of the activity would also result in additional operational costs due to increased fuel consumption.

In summary, the operational community determined that implementing procedural mitigation for explosive sonobuoys beyond what is detailed in Table 5-4 would be incompatible with the practicality assessment criteria for safety, sustainability, and mission requirements.

5.3.3.2 Explosive Torpedoes

The Navy will continue to implement procedural mitigation to avoid or reduce potential impacts on marine mammals and sea turtles from explosive torpedoes, as outlined in Table 5-5.

Table 5-5: Procedural Mitigation for Explosive Torpedoes

Procedural Mitigation Description
Stressor or Activity • Explosive torpedoes
Resource Protection Focus • Marine mammals • Sea turtles
Number of Lookouts and Observation Platform • 1 Lookout positioned in an aircraft • If additional platforms are participating in the activity, personnel positioned in those assets (e.g., safety observers, evaluators) will support observing the mitigation zone for applicable biological resources while performing their regular duties.
Mitigation Requirements • Mitigation zone: – 2,100 yd. around the intended impact location • Prior to the initial start of the activity (e.g., during deployment of the target): – Conduct passive acoustic monitoring for marine mammals; use information from detections to assist visual observations. – Visually observe the mitigation zone for marine mammals, sea turtles, and jellyfish aggregations; if observed, relocate or delay the start of firing. • During the activity: – Observe the mitigation zone for marine mammals, sea turtles, and jellyfish aggregations; if observed, cease firing. • Commencement/recommencement conditions after a marine mammal or sea turtle sighting before or during the activity: – The Navy will allow a sighted marine mammal or sea turtle to leave the mitigation zone prior to the initial start of the activity (by delaying the start) or during the activity (by not recommencing firing) until one of the following conditions has been met: (1) the animal is observed exiting the mitigation zone; (2) the animal is thought to have exited the mitigation zone based on a determination of its course, speed, and movement relative to the intended impact location; or (3) the mitigation zone has been clear from any additional sightings for 10 minutes when the activity involves aircraft that have fuel constraints, or 30 minutes when the activity involves aircraft that are not typically fuel constrained. • After completion of the activity (e.g., prior to maneuvering off station): – When practical (e.g., when platforms are not constrained by fuel restrictions or mission-essential follow-on commitments), observe the vicinity of where detonations occurred; if any injured or dead marine mammals or ESA-listed species are observed, follow established incident reporting procedures. – If additional platforms are supporting this activity (e.g., providing range clearance), these assets will assist in the visual observation of the area where detonations occurred.

In the 2015 MITT Final EIS/OEIS, the explosive torpedo mitigation zone was based on net explosive weight and the associated average ranges to PTS. When developing the mitigation for this Final SEIS/OEIS, the Navy analyzed the potential for increasing the size of this mitigation zone. The Navy

determined that the current mitigation zone is the largest area within which it is practical to implement mitigation for this activity; therefore, it will continue implementing this same mitigation zone under the Proposed Action.

The post-activity observations for explosive torpedoes are a continuation from the 2015 MITT Final EIS/OEIS and will help the Navy determine if any resources were injured during the activity. The Navy will follow the incident reporting procedures outlined in Section 5.1.2.2.3 (Incident Reports) if an incident is detected at any time during the event, including during the post-activity observations. The Navy is clarifying in the table that it will require observation of the mitigation zone prior to the initial start of the activity to ensure the area is clear of applicable biological resources. The Navy has always verified that the mitigation zone is visually clear prior to conducting explosive activities and is more clearly capturing this current practice in the mitigation measures for this activity. The Navy is adding a requirement that additional platforms already participating in the activity will support observing the mitigation zone before, during, and after the activity while performing their regular duties. Typically, when aircraft are firing explosive torpedoes, there are additional observation aircraft, support vessels (e.g., range craft for torpedo retrieval), or other safety aircraft in the vicinity. When available, having additional personnel support observations of the mitigation zone will help increase the likelihood of detecting biological resources.

Explosive torpedo activities involve detonations at a target located down range of the firing platform. Due to the distance between the mitigation zone and the observation platform, Lookouts will have a better likelihood of detecting large visual cues (e.g., whale blows or large pods of dolphins) than individual marine mammals, cryptic marine mammal species, and sea turtles. Some species of sea turtles forage on jellyfish, and some of the locations where explosive torpedo activities could occur support high densities of jellyfish throughout parts of the year. Observing for jellyfish aggregations will further help avoid or reduce potential impacts on sea turtles within the mitigation zone. The post-activity observations for marine mammals and sea turtles will help the Navy determine if any resources were injured during the activity.

Bin E11 has the longest predicted impact ranges for explosive torpedoes used in the Study Area. For the largest explosive in bin E11, the mitigation zone extends beyond the ranges to 50 percent non-auditory injury and 50 percent mortality for sea turtles and marine mammals. The mitigation zone extends beyond the average ranges to PTS for sea turtles, low-frequency cetaceans, and mid-frequency cetaceans, and into a portion of the average ranges to PTS for high-frequency cetaceans. The mitigation zone extends beyond the average range to TTS for sea turtles and mid-frequency cetaceans, and into a portion of the average ranges to TTS for low-frequency cetaceans and high-frequency cetaceans. Therefore, depending on the species, mitigation will help avoid or reduce all or a portion of the potential for exposure to mortality, non-auditory injury, PTS, and higher levels of TTS for the largest explosives in bin E11. Explosive torpedoes in smaller source bins (e.g., E8) have shorter predicted impact ranges; therefore, the mitigation zone will extend further beyond or cover a greater portion of the impact ranges for these explosives.

As described previously, the mitigation zone developed for this Final SEIS/OEIS is based on the largest area within which it is practical for the Navy to implement mitigation. It is not practical to increase this mitigation zone because observations within the margin of increase would be ineffective unless the Navy allocated additional platforms to observe for biological resources. The use of additional personnel and observation platforms would be unsustainable due to increased operational costs and an exceedance of the available manpower and resources for this activity. Adding aircraft to observe the

mitigation zone could result in airspace conflicts with the event participants. This would either require the aircraft participating in the activity to modify their flight plans (which would reduce activity realism) or force the observing aircraft to position itself a safe distance away from the activity area (which would decrease observation effectiveness). Adding vessels to observe the mitigation zone would increase safety risks due to the presence of observation vessels within the vicinity of explosive torpedoes.

Increasing the mitigation zone size would result in a larger area over which detonations would need to be ceased in response to a sighting, and therefore would likely increase the number of times detonations would be ceased and would extend the length of the activity. These impacts would significantly diminish event realism in a way that would prevent the activity from meeting its intended objectives. For example, the Navy conducts Torpedo (Explosive) Testing events to test the functionality of torpedoes and torpedo launch systems. These events often involve aircrews locating, approaching, and firing a torpedo on an artificial target. They require focused situational awareness of the activity area and continuous coordination between the participating platforms as required during military missions and combat operations. Extending the length of the activity would require aircraft to depart the area to refuel. If the firing aircraft departed the activity location to refuel, the aircrew would lose the ability to maintain situational awareness and effectively coordinate with other participating platforms. If multiple refueling events were required, the activity length would extend by two to five times or more, which would increase safety risks due to increased pilot fatigue and accelerated fatigue-life of aircraft. Therefore, an increase in mitigation would impede the Navy's ability to meet testing requirements per required acquisition milestones or on an as-needed basis to meet operational requirements. Extending the length of the activity would also result in additional operational costs due to increased fuel consumption.

In summary, the operational community determined that implementing procedural mitigation for explosive torpedoes beyond what is detailed in Table 5-5 would be incompatible with the practicality assessment criteria for safety, sustainability, and mission requirements.

5.3.3.3 Explosive Medium-Caliber and Large-Caliber Projectiles

The Navy will continue to implement procedural mitigation to avoid or reduce potential impacts on marine mammals and sea turtles from explosive gunnery activities, as outlined in Table 5-6.

In the 2015 MITT Final EIS/OEIS, explosive gunnery activity mitigation zones were based on net explosive weight and the associated average ranges to PTS. When developing mitigation for this Final SEIS/OEIS, the Navy analyzed the potential for increasing the size of these mitigation zones. The Navy identified an opportunity to increase the mitigation zone size by 400 yd. for surface-to-surface activities to enhance protections to the maximum extent practicable. This increase is reflected in Table 5-6. The mitigation zones for explosive medium-caliber and large-caliber projectiles are now based on the largest areas within which it is practical to implement mitigation.

The Navy is clarifying in the table that it will require observation of the mitigation zone prior to the initial start of the activity to ensure the area is clear of applicable biological resources. The Navy has always verified that the mitigation zone is visually clear prior to conducting explosive activities and is more clearly capturing this current practice in the mitigation measures for this activity. The Navy developed a new mitigation measure requiring the Lookout to observe the mitigation zone after completion of the activity. In accordance with the 2015 MITT Final EIS/OEIS consultation requirements, the Navy currently conducts post-activity observations for some, but not all explosive activities. When developing the mitigation for this Final SEIS/OEIS, the Navy determined that it could expand this requirement to other

explosive activities for enhanced consistency and to help determine if any resources were injured during explosive events, when practical.

Table 5-6: Procedural Mitigation for Explosive Medium-Caliber and Large-Caliber Projectiles

Procedural Mitigation Description
Stressor or Activity • Gunnery activities using explosive medium-caliber and large-caliber projectiles – Mitigation applies to activities using a surface target
Resource Protection Focus • Marine mammals • Sea turtles
Number of Lookouts and Observation Platform • 1 Lookout on the vessel or aircraft conducting the activity – For activities using explosive large-caliber projectiles, depending on the activity, the Lookout could be the same as the one described in Section 5.3.2.2 (Weapons Firing Noise) • If additional platforms are participating in the activity, personnel positioned in those assets (e.g., safety observers, evaluators) will support observing the mitigation zone for applicable biological resources while performing their regular duties.
Mitigation Requirements • Mitigation zones: – 200 yd. around the intended impact location for air-to-surface activities using explosive medium-caliber projectiles – 600 yd. around the intended impact location for surface-to-surface activities using explosive medium-caliber projectiles – 1,000 yd. around the intended impact location for surface-to-surface activities using explosive large-caliber projectiles • Prior to the initial start of the activity (e.g., when maneuvering on station): – Observe the mitigation zone for marine mammals and sea turtles; if observed, relocate or delay the start of firing. • During the activity: – Observe the mitigation zone for marine mammals and sea turtles; if observed, cease firing. • Commencement/recommencement conditions after a marine mammal or sea turtle sighting before or during the activity: – The Navy will allow a sighted marine mammal or sea turtle to leave the mitigation zone prior to the initial start of the activity (by delaying the start) or during the activity (by not recommencing firing) until one of the following conditions has been met: (1) the animal is observed exiting the mitigation zone; (2) the animal is thought to have exited the mitigation zone based on a determination of its course, speed, and movement relative to the intended impact location; (3) the mitigation zone has been clear from any additional sightings for 10 minutes for aircraft-based firing or 30 minutes for vessel-based firing; or (4) for activities using mobile targets, the intended impact location has transited a distance equal to double that of the mitigation zone size beyond the location of the last sighting. • After completion of the activity (e.g., prior to maneuvering off station): – When practical (e.g., when platforms are not constrained by fuel restrictions or mission-essential follow-on commitments), observe the vicinity of where detonations occurred; if any injured or dead marine mammals or ESA-listed species are observed, follow established incident reporting procedures. – If additional platforms are supporting this activity (e.g., providing range clearance), these assets will assist in the visual observation of the area where detonations occurred.

The Navy is adding a requirement that additional platforms already participating in the activity will support observing the mitigation zone before, during, and after the activity while performing their regular duties. Typically, when aircraft are firing explosive munitions there are additional observation aircraft, multiple aircraft firing munitions, or other safety aircraft in the vicinity. When available, having additional personnel support observations of the mitigation zone will help increase the likelihood of detecting biological resources. The Navy will follow the incident reporting procedures outlined in Section 5.1.2.2.3 (Incident Reports) if an incident is detected at any time during the event, including during the post-activity observations.

Large-caliber gunnery activities involve vessels firing projectiles at targets located up to 6 nautical miles (NM) down range. Medium-caliber gunnery activities involve vessels or aircraft firing projectiles at targets located up to 4,000 yd. down range, although typically much closer. As described in Section 5.2.1

(At-Sea Procedural Mitigation Development), certain platforms, such as the small boats and aircraft used during explosive medium-caliber gunnery exercises, have manning or space restrictions; therefore, the Lookout for these activities is typically an existing member of the aircraft or boat crew who is responsible for other essential tasks (e.g., navigation). Due to their relatively lower vantage point, Lookouts on vessels (during medium-caliber or large-caliber gunnery exercises) will be more likely to detect large visual cues (e.g., whale blows, breaching whales) than individual marine mammals, cryptic marine mammal species, and sea turtles when observing around targets located at the furthest firing distances. The Navy will implement larger mitigation zones for large-caliber gunnery activities than for medium-caliber gunnery activities due to the nature of how the activities are conducted. For example, large-caliber gunnery activities are conducted from surface combatants, so Lookouts can observe a larger mitigation zone because they typically have access to high-powered binoculars mounted on the ship deck. This will enable observation of the distant mitigation zone in combination with hand-held binoculars and naked-eye scanning. Lookouts in aircraft (during medium-caliber gunnery exercises), have a relatively higher vantage point for observing the mitigation zones but will still be more likely to detect individual marine mammals and sea turtles when observing mitigation zones located close to the firing platform than at the furthest firing distances.

The mitigation applies only to activities using surface targets. Most airborne targets are recoverable aerial drones that are not intended to be hit by ordnance. Given the speed of the projectiles and mobile target, and the long ranges that projectiles typically travel, it is not possible to definitively predict or to effectively observe where the projectile fragments will fall. For gunnery activities using explosive medium-caliber and large-caliber projectiles, the potential military expended material fall zone can only be predicted within thousands of yards, which can be up to 6 NM from the firing location. These areas are too large to be effectively observed for marine mammals and sea turtles with the number of personnel and platforms available for this activity. The potential risk to marine mammals and sea turtles during events using airborne targets is limited to the animal being directly struck by falling military expended materials. There is no potential for direct impact from the explosives because the detonations occur in air. Based on the extremely low potential for projectile fragments to co-occur in space and time with a marine mammal or sea turtle at or near the surface of the water, the potential for a direct strike is negligible; therefore, mitigation for gunnery activities using airborne targets would not be effective at avoiding or reducing potential impacts.

Bin E5 (e.g., 5-inch projectiles) has the longest predicted impact ranges for explosive projectiles that apply to the 1,000 yd. mitigation zone. Bin E2 (e.g., 40-millimeter projectiles) has the longest predicted impact ranges for explosive projectiles that apply to the 600 yd. and 200 yd. mitigation zones. The 1,000 yd., 600 yd., and 200 yd. mitigation zones extend beyond the respective ranges to 50 percent non-auditory injury and 50 percent mortality for sea turtles and marine mammals. The 1,000 yd., 600 yd., and 200 yd. mitigation zones extend beyond the respective average ranges to PTS for sea turtles, mid-frequency cetaceans, and low-frequency cetaceans, and into a portion of the average ranges to PTS for high-frequency cetaceans. The mitigation zones also extend beyond or into a portion of the average ranges to TTS for sea turtles and marine mammals. Therefore, depending on the species, mitigation will help avoid or reduce all or a portion of the potential for exposure to mortality, non-auditory injury, PTS, and higher levels of TTS for the largest explosives in bin E5 and bin E2. Explosives in smaller source bins (e.g., E1) have shorter predicted impact ranges; therefore, the mitigation zones will extend further beyond or cover a greater portion of the impact ranges for these explosives.

As described previously, the mitigation zones developed for this Final SEIS/OEIS are based on the largest areas within which it is practical for the Navy to implement mitigation. It is not practical to increase these mitigation zones because observations within the margin of increase would be unsafe and ineffective. One of the mission-essential safety protocols for explosive gunnery activities is a requirement for event participants (including the Lookout) to maintain focus on the activity area to ensure safety of Navy personnel and equipment, and the public. For example, when air-to-surface medium-caliber gunnery exercises involve fighter aircraft descending on a target, or rotary-wing aircraft flying a racetrack pattern and descending on a target using a forward-tilted firing angle, maintaining attention on the activity area is paramount to aircraft safety. The typical activity areas for medium-caliber and large-caliber gunnery activities coincide with the applicable mitigation zones; therefore, the Lookout can safely and effectively observe the mitigation zones for biological resources while simultaneously maintaining focus on the activity area. However, if the mitigation zone sizes increased, the Lookout would need to redirect attention to observe beyond the activity area. This would not meet the safety criteria since personnel would be required to direct attention away from mission requirements. Alternatively, the Navy would need to add personnel to serve as additional Lookouts on the existing observation platforms or allocate additional platforms to the activity to observe for biological resources. These actions would not be safe or sustainable due to an exceedance of manpower, resource, and space restrictions for these activities. Similarly, positioning platforms closer to the intended impact location would increase safety risks related to proximity to the detonation location and path of the explosive projectile.

Increasing the mitigation zone sizes would result in larger areas over which detonations would need to be ceased in response to a sighting, and therefore would likely increase the number of times firing would be ceased and would extend the length of the activity. These impacts would significantly diminish event realism in a way that would prevent activities from meeting their intended objectives. For example, the Navy must train its gun crews to coordinate with other participating platforms (e.g., small boats launching a target, other firing platforms), locate and engage surface targets (e.g., high speed maneuverable surface targets), and practice precise defensive marksmanship to disable threats.

Depending on the type of target being used, additional stopping of the activity could result in the target needing to be recovered and relaunched, which would cause a significant loss of training time. For activities that involve aircraft, extending the length of the activity would require aircraft to depart the area to refuel. If multiple refueling events were required, the length of the activity would be extended by two to five times or more, which would decrease the ability for Lookouts to safely and effectively maintain situational awareness of the activity area and increase safety risks due to increased pilot fatigue and accelerated fatigue-life of aircraft. These types of impacts would reduce the number of opportunities that gun crews have to fire on the target and cause significant delays to the training schedule. Therefore, an increase in mitigation would impede the ability for gun crews to train and become proficient in using their weapons as required during military missions and combat operations and would prevent units from meeting their individual training and certification requirements (which would prevent them from deploying with the required level of readiness necessary to accomplish their missions). Extending the length of the activity would also result in additional operational costs due to increased fuel consumption.

In summary, the operational community determined that implementing procedural mitigation for explosive medium-caliber and large-caliber projectiles beyond what is detailed in Table 5-6 would be

incompatible with the practicality assessment criteria for safety, sustainability, and mission requirements.

5.3.3.4 Explosive Missiles and Rockets

The Navy will continue to implement procedural mitigation to avoid or reduce potential impacts on marine mammals and sea turtles from explosive missiles and rockets, as outlined in Table 5-7.

Table 5-7: Procedural Mitigation for Explosive Missiles and Rockets

Procedural Mitigation Description
Stressor or Activity • Aircraft-deployed explosive missiles and rockets – Mitigation applies to activities using a surface target
Resource Protection Focus • Marine mammals • Sea turtles
Number of Lookouts and Observation Platform • 1 Lookout positioned in an aircraft • If additional platforms are participating in the activity, personnel positioned in those assets (e.g., safety observers, evaluators) will support observing the mitigation zone for applicable biological resources while performing their regular duties.
Mitigation Requirements • Mitigation zones: – 900 yd. around the intended impact location for missiles or rockets with 0.6–20 lb. net explosive weight – 2,000 yd. around the intended impact location for missiles with 21–500 lb. net explosive weight • Prior to the initial start of the activity (e.g., during a fly-over of the mitigation zone): – Observe the mitigation zone for marine mammals and sea turtles; if observed, relocate or delay the start of firing. • During the activity: – Observe the mitigation zone for marine mammals and sea turtles; if observed, cease firing. • Commencement/recommencement conditions after a marine mammal or sea turtle sighting before or during the activity: – The Navy will allow a sighted marine mammal or sea turtle to leave the mitigation zone prior to the initial start of the activity (by delaying the start) or during the activity (by not recommencing firing) until one of the following conditions has been met: (1) the animal is observed exiting the mitigation zone; (2) the animal is thought to have exited the mitigation zone based on a determination of its course, speed, and movement relative to the intended impact location; or (3) the mitigation zone has been clear from any additional sightings for 10 minutes when the activity involves aircraft that have fuel constraints, or 30 minutes when the activity involves aircraft that are not typically fuel constrained. • After completion of the activity (e.g., prior to maneuvering off station): – When practical (e.g., when platforms are not constrained by fuel restrictions or mission-essential follow-on commitments), observe the vicinity of where detonations occurred; if any injured or dead marine mammals or ESA-listed species are observed, follow established incident reporting procedures. – If additional platforms are supporting this activity (e.g., providing range clearance), these assets will assist in the visual observation of the area where detonations occurred.

In the 2015 MITT Final EIS/OEIS, explosive missile and rocket mitigation zones were based on net explosive weight and the associated average ranges to PTS. When developing the mitigation for this Final SEIS/OEIS, the Navy analyzed the potential for increasing the mitigation zone sizes. The Navy identified an opportunity to increase the mitigation zone by 1,100 yd. for missiles and rockets using 21–250 lb. net explosive weight to enhance protections to the maximum extent practicable. This increase is reflected in Table 5-7. The mitigation zones are now based on the largest areas within which it is practical to implement mitigation.

The Navy is clarifying in the table that it will require observation of the mitigation zone prior to the initial start of the activity to ensure the area is clear of applicable biological resources. The Navy has always verified that the mitigation zone is visually clear prior to conducting explosive activities and is more clearly capturing this current practice in the mitigation measures for this activity. The Navy developed a

new mitigation measure requiring the Lookout to observe the mitigation zone after completion of the activity. In accordance with the 2015 MITT Final EIS/OEIS consultation requirements, the Navy currently conducts post-activity observations for some, but not all explosive activities. When developing the mitigation for this Final SEIS/OEIS, the Navy determined that it could expand this requirement to other explosive activities for enhanced consistency and to help determine if any resources were injured during explosive events, when practical. The Navy is adding a requirement that additional platforms already participating in the activity will support observing the mitigation zone before, during, and after the activity while performing their regular duties. Typically, when aircraft are firing explosive munitions there are additional observation aircraft, multiple aircraft firing munitions, or other safety aircraft in the vicinity. For example, during typical explosive missile exercises, two aircraft circle the activity location. One aircraft clears the intended impact location while the other fires, and vice versa. A third aircraft is typically present for safety or proficiency inspections. When available, having additional personnel support observations of the mitigation zone will help increase the likelihood of detecting biological resources. The Navy will follow the incident reporting procedures outlined in Section 5.1.2.2.3 (Incident Reports) if an incident is detected at any time during the event, including during the post-activity observations.

Missile and rocket exercises involve firing munitions at a target typically located up to 15 NM down range, and infrequently up to 75 NM down range. Due to the distance between the mitigation zone and the observation platform, the Lookout will have a better likelihood of detecting marine mammals and sea turtles during close-range observations and are less likely to detect these resources once positioned at the firing location, particularly individual marine mammals, cryptic marine mammal species, and sea turtles. There is a chance that animals could enter the mitigation zone after the aircraft conducts its close-range mitigation zone observations and before firing begins (once the aircraft has transited to its firing position). The Navy will implement larger mitigation zones for missiles using 21–500 lb. net explosive weight than for missiles and rockets using 0.6–20 lb. net explosive weight due to the nature of how these activities are conducted. During activities using missiles in the larger net explosive weight category, firing aircraft (e.g., maritime patrol aircraft) have the capability of mitigating a larger area due to their larger fuel capacity. During activities using missiles or rockets in the smaller net explosive weight category, firing aircraft (e.g., rotary-wing aircraft) are typically constrained by their fuel capacity.

The mitigation applies to aircraft-deployed missiles and rockets because aircraft can fly over the intended impact area prior to commencing firing. Mitigation would be ineffective for vessel-deployed missiles and rockets because of the inability for a Lookout to detect marine mammals or sea turtles from a vessel from the distant firing position. It would not be effective or practical to have a vessel conduct close-range observations of the mitigation zone prior to firing due to the length of time it would take to complete observations and transit back to the firing position, and the costs associated with increased fuel consumption. The mitigation applies to activities using surface targets. Most airborne targets are recoverable aerial drones that are not intended to be hit by ordnance. For example, telemetry-configured anti-air missiles used in training are designed to detonate or simulate a detonation near a target, but not as a result of a direct strike on a target. Given the speed of missiles and mobile targets, the high altitudes involved, and the long ranges that missiles typically travel, it is not possible to definitively predict or to effectively observe where the missile fragments will fall. The potential expended material fall zone can only be predicted within tens of miles for long range events, which can be 75 NM from the firing location; and thousands of yards for short range events, which can occur 15 NM from the firing location. These areas are too large to be effectively observed for marine mammals and sea turtles with the number of personnel and platforms available for this activity. The

potential risk to marine mammals and sea turtles during events using airborne targets is limited to the animal being directly struck by falling military expended materials. There is no potential for direct impact from explosives because the detonations occur in air. Based on the extremely low potential for military expended materials to co-occur in space and time with a marine mammal or sea turtle at or near the surface of the water, the potential for a direct strike is negligible; therefore, mitigation would not be effective at avoiding or reducing potential impacts.

Bin E10 (e.g., Harpoon missiles) has the longest predicted impact ranges for explosive missiles that apply to the 2,000 yd. mitigation zone. Bin E6 (e.g., Hellfire missiles) has the longest predicted impact ranges for explosive missiles and rockets that apply to the 900 yd. mitigation zone. The 2,000 yd. and 900 yd. mitigation zones extend beyond the respective ranges to 50 percent non-auditory injury and 50 percent mortality for sea turtles and marine mammals. The mitigation zones extend beyond the respective average ranges to PTS for sea turtles, mid-frequency cetaceans, and low-frequency cetaceans, and into a portion of the respective average ranges to PTS for high-frequency cetaceans. The mitigation zones also extend beyond or into a portion of the average ranges to TTS for sea turtles and marine mammals. Therefore, depending on the species, mitigation will help avoid or reduce all or a portion of the potential for exposure to mortality, non-auditory injury, PTS, and higher levels of TTS for the largest explosives in bin E10 and bin E6. Explosives in smaller source bins (e.g., missiles in bin E8, rockets in bin E3) have shorter predicted impact ranges; therefore, the mitigation zones will cover a greater portion of the impact ranges for these explosives.

As described previously, the mitigation zones developed for this Final SEIS/OEIS are based on the largest areas within which it is practical for the Navy to implement mitigation. It is not practical to increase these mitigation zones because observations within the margin of increase would be unsafe and ineffective unless the Navy allocated additional platforms to the activity to observe for biological resources. The use of additional personnel and equipment (e.g., aircraft) would be unsustainable due to increased operational costs and an exceedance of the available manpower and resources for this activity. Adding aircraft to observe the mitigation zone could result in airspace conflicts with the event participants. This would either require the aircraft conducting the activity to modify their flight plans (which would reduce activity realism) or force the observing aircraft to position itself a safe distance away from the activity area (which would decrease observation effectiveness). Similarly, positioning platforms closer to the intended impact location (as would be required if mitigation applied to vessel-deployed missiles and rockets) would increase safety risks related to proximity to the detonation location and path of the explosive missile or rocket.

Increasing the mitigation zone sizes would result in larger areas over which firing would need to be ceased in response to a sighting, and therefore would likely increase the number of times detonations would be ceased and would extend the length of the activity. These impacts would significantly diminish event realism in a way that would prevent the activity from meeting its intended objectives. Explosive missile and rocket events require focused situational awareness of the activity area and continuous coordination between the participating platforms as required during military missions and combat operations. For activities using missiles in the larger net explosive weight category, the flyover distance between the mitigation zone and the firing location can extend upwards of 75 NM; therefore, even aircraft with larger fuel capacities would need to depart the activity area to refuel if the length of the activity was extended. If the firing aircraft departed the activity location to refuel, the aircrew would lose the ability to maintain situational awareness of the activity area and effectively coordinate with other participating platforms. If multiple refueling events were required, the activity length would

extend by two to five times or more, which would increase safety risks due to increased pilot fatigue and accelerated fatigue-life of aircraft. These types of impacts would cause a significant loss of training or testing time, reduce the number of opportunities that aircrews have to fire on the target, and cause a significant delay to the training or testing schedule. Therefore, an increase in mitigation would impede the ability for aircrews to train and become proficient in using their weapons as required during military missions and combat operations, would prevent units from meeting their individual training and certification requirements (which would prevent them from deploying with the required level of readiness necessary to accomplish their missions), and would impede the ability of program managers and weapons system acquisition programs to meet testing requirements per required acquisition milestones or on an as-needed basis to meet operational requirements. Extending the length of the activity would also result in additional operational costs due to increased fuel consumption.

In summary, the operational community determined that implementing procedural mitigation for explosive missiles and rockets beyond what is detailed in Table 5-7 would be incompatible with the practicality assessment criteria for safety, sustainability, and mission requirements.

5.3.3.5 Explosive Bombs

The Navy will continue to implement procedural mitigation to avoid or reduce potential impacts on marine mammals and sea turtles from explosive bombs, as outlined in Table 5-8.

Table 5-8: Procedural Mitigation for Explosive Bombs

Procedural Mitigation Description
Stressor or Activity • Explosive bombs
Resource Protection Focus • Marine mammals • Sea turtles
Number of Lookouts and Observation Platform • 1 Lookout positioned in the aircraft conducting the activity • If additional platforms are participating in the activity, personnel positioned in those assets (e.g., safety observers, evaluators) will support observing the mitigation zone for applicable biological resources while performing their regular duties.
Mitigation Requirements • Mitigation zone: – 2,500 yd. around the intended target • Prior to the initial start of the activity (e.g., when arriving on station): – Observe the mitigation zone for marine mammals and sea turtles; if observed, relocate or delay the start of bomb deployment. • During the activity (e.g., during target approach): – Observe the mitigation zone for marine mammals and sea turtles; if observed, cease bomb deployment. • Commencement/recommencement conditions after a marine mammal or sea turtle sighting before or during the activity: – The Navy will allow a sighted marine mammal or sea turtle to leave the mitigation zone prior to the initial start of the activity (by delaying the start) or during the activity (by not recommencing bomb deployment) until one of the following conditions has been met: (1) the animal is observed exiting the mitigation zone; (2) the animal is thought to have exited the mitigation zone based on a determination of its course, speed, and movement relative to the intended target; (3) the mitigation zone has been clear from any additional sightings for 10 minutes; or (4) for activities using mobile targets, the intended target has transited a distance equal to double that of the mitigation zone size beyond the location of the last sighting. • After completion of the activity (e.g., prior to maneuvering off station): – When practical (e.g., when platforms are not constrained by fuel restrictions or mission-essential follow-on commitments), observe the vicinity of where detonations occurred; if any injured or dead marine mammals or ESA-listed species are observed, follow established incident reporting procedures. – If additional platforms are supporting this activity (e.g., providing range clearance), these assets will assist in the visual observation of the area where detonations occurred.

In the 2015 MITT Final EIS/OEIS, the explosive bombing mitigation zone was based on net explosive weight and the associated average ranges to PTS. When developing the mitigation for this Final SEIS/OEIS, the Navy analyzed the potential for increasing the size of this mitigation zone. The Navy determined that the current mitigation zone for explosive bombs is the largest area within which it is practical to implement mitigation for this activity; therefore, it will continue implementing this same mitigation zone under the Proposed Action.

The Navy is clarifying in the table that it will require observation of the mitigation zone prior to the initial start of the activity to ensure the area is clear of applicable biological resources. The Navy has always verified that the mitigation zone is visually clear prior to conducting explosive activities and is more clearly capturing this current practice in the mitigation measures for this activity. The Navy developed a new mitigation measure requiring the Lookout to observe the mitigation zone after completion of this activity. In accordance with the 2015 MITT Final EIS/OEIS consultation requirements, the Navy currently conducts post-activity observations for some, but not all explosive activities. When developing mitigation for this Final SEIS/OEIS, the Navy determined that it could expand this requirement to other explosive activities for enhanced consistency and to help determine if any resources were injured during explosive events, when practical. The Navy is adding a requirement that additional platforms already participating in the activity will support observing the mitigation zone before, during, and after the activity while performing their regular duties. Typically, when aircraft are firing explosive munitions there are additional observation aircraft, multiple aircraft firing munitions, or other safety aircraft in the vicinity. When available, having additional personnel support observations of the mitigation zone will help increase the likelihood of detecting biological resources. The Navy will follow the incident reporting procedures outlined in Section 5.1.2.2.3 (Incident Reports) if an incident is detected at any time during the event, including during the post-activity observations.

Bombing exercises involve an aircraft deploying munitions at a surface target located beneath the firing platform. During target approach, aircraft maintain a relatively steady altitude of approximately 1,500 ft. Lookouts, by necessity for safety and mission success, primarily focus their attention on the water surface surrounding the intended detonation location (i.e., the mitigation zone). Being positioned in an aircraft gives the Lookout a good vantage point for observing marine mammals and sea turtles throughout the mitigation zone.

Bin E12 (e.g., 2,000 lb. bombs) has the longest predicted impact ranges for explosive bombs used in the Study Area. The 2,500 yd. mitigation zone extends beyond the ranges to 50 percent non-auditory injury and 50 percent mortality for sea turtles and marine mammals. The mitigation zone extends beyond the average ranges to PTS for sea turtles, mid-frequency cetaceans, and low-frequency cetaceans, and into a portion of the average range to PTS for high-frequency cetaceans. The mitigation zone also extends beyond or into a portion of the average ranges to TTS for sea turtles and marine mammals. Therefore, depending on the species, mitigation will help avoid or reduce all or a portion of the potential for exposure to mortality, non-auditory injury, PTS, and higher levels of TTS for the largest bombs in bin E12. Smaller bombs (e.g., 250 lb. bombs, 500 lb. bombs) have shorter predicted impact ranges; therefore, the mitigation zone will extend further beyond or cover a greater portion of the impact ranges for these explosives.

As described previously, the mitigation zone developed for this Final SEIS/OEIS is based on the largest area within which it is practical for the Navy to implement mitigation. It is not practical to increase this mitigation zone because observations within the margin of increase would be unsafe and ineffective unless the Navy allocated additional platforms to the activity to observe for biological resources. The use

of additional personnel and aircraft would be unsustainable due to increased operational costs and an exceedance of the available manpower and resources for this activity. Adding aircraft to observe the mitigation zone could result in airspace conflicts with the event participants. This would either require the aircraft participating in the activity to modify their flight plans (which would reduce activity realism) or force the observing aircraft to position itself a safe distance away from the activity area (which would decrease observation effectiveness). Adding vessels to observe the mitigation zone would increase safety risks due to the presence of observation vessels within the vicinity of the intended explosive bomb detonation location.

Increasing the mitigation zone would result in a larger area over which explosive bomb deployment would need to be ceased in response to a sighting, and therefore would likely increase the number of times explosive bombing activities would be ceased and would extend the length of the activity. These impacts would significantly diminish event realism in a way that would prevent the activity from meeting its intended objectives. For example, critical components of a Bombing Exercise Air-to-Surface training activity are the assembly, loading, delivery, and assessment of an explosive bomb. The activity requires focused situational awareness of the activity area and continuous coordination between multiple training components. The training exercise starts with ground personnel, who must practice the building and loading of explosive munitions. Training includes the safe handling of explosive material, configuring munitions to precise specifications, and loading munitions onto aircraft. Aircrew must then identify a target and safely deliver fused munitions, discern if the bomb was assembled correctly, and determine bomb damage assessments based on how and where the explosive detonated. Extending the length of the activity would require aircraft to depart the area to refuel. If the firing aircraft departed the activity area to refuel, aircrew would lose the ability to maintain situational awareness of the activity area, effectively coordinate with other participating platforms, and complete all training components as required during military missions and combat operations. If multiple refueling events were required, the activity length would be extended by two to five times or more, which would cause a significant loss of training time and would increase safety risks due to increased pilot fatigue and accelerated fatigue-life of aircraft. This would reduce the number of opportunities that aircrews have to approach targets and deploy bombs, which would cause a significant delay to the training schedule. Therefore, an increase in mitigation would impede the ability for aircrews to train and become proficient in using their weapons. This would prevent units from meeting their individual training and certification requirements and deploying with the required level of readiness necessary to accomplish their missions. Extending the length of the activity would also result in additional operational costs due to increased fuel consumption.

In summary, the operational community determined that implementing procedural mitigation for explosive bombs beyond what is detailed in Table 5-8 would be incompatible with the practicality assessment criteria for safety, sustainability, and mission requirements.

5.3.3.6 Sinking Exercises

The Navy will continue to implement procedural mitigation to avoid or reduce potential impacts on marine mammals and sea turtles from sinking exercises, as outlined in Table 5-9.

Table 5-9: Procedural Mitigation for Sinking Exercises

Procedural Mitigation Description
Stressor or Activity • Sinking exercises
Resource Protection Focus • Marine mammals • Sea turtles
Number of Lookouts and Observation Platform • 2 Lookouts (one positioned in an aircraft and one on a vessel) • If additional platforms are participating in the activity, personnel positioned in those assets (e.g., safety observers, evaluators) will support observing the mitigation zone for applicable biological resources while performing their regular duties.
Mitigation Requirements • Mitigation zone: – 2.5 NM around the target ship hulk • Prior to the initial start of the activity (90 minutes prior to the first firing): – Conduct aerial observations of the mitigation zone for marine mammals, sea turtles, and jellyfish aggregations; if observed, delay the start of firing. • During the activity: – Conduct passive acoustic monitoring for marine mammals; use information from detections to assist visual observations. – Visually observe the mitigation zone for marine mammals and sea turtles from the vessel; if observed, cease firing. – Immediately after any planned or unplanned breaks in weapons firing of longer than 2 hours, observe the mitigation zone for marine mammals and sea turtles from the aircraft and vessel; if observed, delay recommencement of firing. • Commencement/recommencement conditions after a marine mammal or sea turtle sighting before or during the activity: – The Navy will allow a sighted marine mammal or sea turtle to leave the mitigation zone prior to the initial start of the activity (by delaying the start) or during the activity (by not recommencing firing) until one of the following conditions has been met: (1) the animal is observed exiting the mitigation zone; (2) the animal is thought to have exited the mitigation zone based on a determination of its course, speed, and movement relative to the target ship hulk; or (3) the mitigation zone has been clear from any additional sightings for 30 minutes. • After completion of the activity (for 2 hours after sinking the vessel or until sunset, whichever comes first): – Observe the vicinity of where detonations occurred; if any injured or dead marine mammals or ESA-listed species are observed, follow established incident reporting procedures. – If additional platforms are supporting this activity (e.g., providing range clearance), these assets will assist in the visual observation of the area where detonations occurred.

In the 2015 MITT Final EIS/OEIS, the mitigation zone was based on net explosive weight and the associated average ranges to PTS. When developing the mitigation for this Final SEIS/OEIS, the Navy analyzed the potential for increasing the size of the mitigation zone. The Navy determined that the current mitigation zone for sinking exercises is the largest area within which it is practical to implement mitigation; therefore, it will continue implementing this same mitigation zone under the Proposed Action. The Navy is clarifying in the table that it will require observation of the mitigation zone prior to the initial start of the activity to ensure the area is clear of applicable biological resources. The Navy has always verified that the mitigation zone is visually clear prior to conducting explosive activities and is more clearly capturing this current practice in the mitigation measures for this activity. The Navy is adding a requirement that additional platforms already participating in the activity will support observing the mitigation zone before, during, and after the activity while performing their regular duties. Sinking exercises typically involved multiple participating platforms. When available, having additional personnel support observations of the mitigation zone will help increase the likelihood of detecting biological resources. The two-hour post-activity observations for sinking exercises are a continuation from the 2015 MITT Final EIS/OEIS and will help the Navy determine if any resources were injured during the activity. Sinking exercises are scheduled to ensure they are conducted only in daylight hours. The Navy will be able to complete the full two hours of post-activity observation during typical

activity conditions and it is unlikely that observations will be shortened due to nightfall. The Navy will follow the incident reporting procedures outlined in Section 5.1.2.2.3 (Incident Reports) if an incident is detected at any time during the event, including during the post-activity observations.

There is a chance that animals could enter the mitigation zone after the aircraft conducts its close-range mitigation zone observations and before firing begins (once the aircraft has transited to its distant firing position). The Lookout positioned on the vessel will have a higher likelihood of detecting individual marine mammals and sea turtles that are in the central portion of the mitigation zone near the target ship hulk. Near the perimeter of the mitigation zone, the Lookout will be more likely to detect large visual cues (e.g., whale blows or large pods of dolphins) than individual marine mammals, cryptic marine mammal species, and sea turtles. The Lookout positioned in the aircraft will be able to assist the vessel-based Lookout by observing the entire mitigation zone, including near the perimeter, because the aircraft will be able to transit a larger area more quickly (e.g., during range clearance), and will offer a better vantage point. Some species of sea turtles forage on jellyfish in the region where this activity occurs. Observing for jellyfish aggregations will further help avoid or reduce potential impacts on sea turtles within the mitigation zone.

Bin E12 has the longest predicted impact ranges for the types of explosives used during sinking exercises in the Study Area. For the largest explosive in bin E12, the mitigation zone extends beyond the ranges to 50 percent non-auditory injury and 50 percent mortality for sea turtles and marine mammals. The mitigation zone extends beyond the average ranges to PTS for sea turtles and marine mammals. The mitigation zone also extends beyond or into a portion of the average ranges to TTS for sea turtles and marine mammals. Therefore, depending on the species, mitigation will help avoid or reduce all or a portion of the potential for exposure to mortality, non-auditory injury, PTS, and higher levels of TTS for the largest explosives in bin E12. Smaller explosives in bin E12 and explosives in smaller source bins (e.g., E10, E5) have shorter predicted impact ranges; therefore, the mitigation zone will extend further beyond or cover a greater portion of the impact ranges for these explosives.

As described previously, the mitigation zone developed for this Final SEIS/OEIS is based on the largest area within which it is practical for the Navy to implement mitigation. It is not practical to increase this mitigation zone because observations within the margin of increase would be ineffective unless the Navy allocated additional platforms to the activity to observe for biological resources. The use of additional personnel, aircraft, or vessels would be unsustainable due to increased operational costs and an exceedance of available manpower and resources for this activity. Adding aircraft to observe the mitigation zone could result in airspace conflicts with the event participants. This would either require the aircraft participating in the activity to modify their flight plans (which would reduce activity realism) or force the observing aircraft to position itself a safe distance away from the activity area (which would decrease observation effectiveness). Adding additional platforms to observe the mitigation zone would increase safety risks due to the presence of additional vessels or aircraft within the vicinity of the intended impact location or in the path of explosive projectiles.

Increasing the mitigation zone size would result in a larger area over which firing would need to be ceased in response to a sighting, and therefore would likely increase the number of times that the sinking exercise would be ceased and would extend the length of the activity. These impacts would significantly diminish event realism in a way that would prevent the activity from meeting its intended objectives. Sinking exercises require focused situational awareness of the activity area and continuous coordination of tactics between ship, submarine, and aircraft crews using multiple weapon systems to deliver explosive ordnance to deliberately sink a deactivated vessel. Extending the length of the activity

would require aircraft to depart the area to refuel, which would disrupt the ability for platforms to maintain continuous coordination of tactics. If multiple refueling events were required, the length of the activity would be extended by two to five times or more, which would decrease the ability for Lookouts to safely and effectively maintain situational awareness of the activity area and increase safety risks due to increased pilot fatigue and accelerated fatigue-life of aircraft. These types of impacts would reduce the frequency at which participants would be able to fire on the deactivated vessel. Because the activity ends when the ship sinks, firing at a decreased frequency would ultimately extend the amount of time it takes for the deactivated vessel to sink. Sinking exercises only take place during daylight hours; therefore, the training exercise would likely be delayed into the next day or next several days, which would significantly impact the schedules of the multiple participants. An increase in mitigation would impede the ability for the participants to become proficient in using their weapons as required during military missions and combat operations and would prevent units from meeting their individual training and certification requirements (which would prevent them from deploying with the required level of readiness necessary to accomplish their missions). Extending the length of the activity would also result in additional operational costs due to increased fuel consumption.

In summary, the operational community determined that implementing procedural mitigation for sinking exercises beyond what is detailed in Table 5-9 would be incompatible with the practicality assessment criteria for safety, sustainability, and mission requirements.

5.3.3.7 Explosive Mine Countermeasure and Neutralization Activities

The Navy will continue to implement procedural mitigation to avoid or reduce potential impacts on marine mammals and sea turtles from explosive mine countermeasure and neutralization activities, as outlined in Table 5-10. The mitigation applies to all explosive mine countermeasure and neutralization activities except those that involve the use of Navy divers, which are discussed in Section 5.3.3.8 (Explosive Mine Neutralization Activities Involving Navy Divers).

The types of charges used in these activities are positively controlled, which means the detonation is controlled by the personnel conducting the activity and is not authorized until the mitigation zone is clear at the time of detonation. In the 2015 MITT Final EIS/OEIS, explosive mine countermeasure and neutralization activity mitigation zones were based on net explosive weight and the associated average ranges to PTS. When developing the mitigation for this Final SEIS/OEIS, the Navy analyzed the potential for increasing the size of the mitigation zone. The Navy determined that the current mitigation zone is the largest area within which it is practical to implement mitigation based on the net explosive weights that will be used for this activity under the Proposed Action; therefore, it will continue implementing this same mitigation zone. The post-activity observations are a continuation from the 2015 MITT Final EIS/OEIS and will help the Navy determine if any resources were injured during the activity. The Navy will follow the incident reporting procedures outlined in Section 5.1.2.2.3 (Incident Reports) if an incident is detected at any time during the event, including during the post-activity observations.

The Navy is clarifying in the table that it will require observation of the mitigation zone prior to the initial start of the activity to ensure the area is clear of applicable biological resources. The Navy has always verified that the mitigation zone is visually clear prior to conducting explosive activities and is more clearly capturing this current practice in the mitigation measures for this activity. The Navy is adding a requirement that additional platforms already participating in the activity will support observing the mitigation zone before, during, and after the activity while performing their regular duties. When available, having additional personnel support observations of the mitigation zone will help increase the likelihood of detecting biological resources. The small observation area and proximity to the observation

platform will result in a high likelihood that the Lookout will be able to detect marine mammals and sea turtles throughout the mitigation zone (regardless of the type of observation platform used).

Table 5-10: Procedural Mitigation for Explosive Mine Countermeasure and Neutralization Activities

Procedural Mitigation Description
Stressor or Activity • Explosive mine countermeasure and neutralization activities
Resource Protection Focus • Marine mammals • Sea turtles
Number of Lookouts and Observation Platform • 1 Lookout positioned on a vessel or in an aircraft • If additional platforms are participating in the activity, personnel positioned in those assets (e.g., safety observers, evaluators) will support observing the mitigation zone for applicable biological resources while performing their regular duties.
Mitigation Requirements • Mitigation zone: – 600 yd. around the detonation site • Prior to the initial start of the activity (e.g., when maneuvering on station; typically, 10 minutes when the activity involves aircraft that have fuel constraints, or 30 minutes when the activity involves aircraft that are not typically fuel constrained): – Observe the mitigation zone for marine mammals and sea turtles; if observed, relocate or delay the start of detonations. • During the activity: – Observe the mitigation zone for marine mammals and sea turtles; if observed, cease detonations. • Commencement/recommencement conditions after a marine mammal or sea turtle sighting before or during the activity: – The Navy will allow a sighted marine mammal or sea turtle to leave the mitigation zone prior to the initial start of the activity (by delaying the start) or during the activity (by not recommencing detonations) until one of the following conditions has been met: (1) the animal is observed exiting the mitigation zone; (2) the animal is thought to have exited the mitigation zone based on a determination of its course, speed, and movement relative to detonation site; or (3) the mitigation zone has been clear from any additional sightings for 10 minutes when the activity involves aircraft that have fuel constraints, or 30 minutes when the activity involves aircraft that are not typically fuel constrained. • After completion of the activity (typically 10 minutes when the activity involves aircraft that have fuel constraints, or 30 minutes when the activity involves aircraft that are not typically fuel constrained): – Observe the vicinity of where detonations occurred; if any injured or dead marine mammals or ESA-listed species are observed, follow established incident reporting procedures. – If additional platforms are supporting this activity (e.g., providing range clearance), these assets will assist in the visual observation of the area where detonations occurred.

Bin E4 (e.g., 5 lb. net explosive weight charges) has the longest predicted impact ranges for explosives used in the Study Area during mine countermeasures and neutralization activities. The 600 yd. mitigation zone extends beyond the respective ranges to 50 percent non-auditory injury and 50 percent mortality for sea turtles and marine mammals. The mitigation zone extends beyond the respective average ranges to PTS for sea turtles, mid-frequency cetaceans, and low-frequency cetaceans, and into a portion of the average ranges to PTS for high-frequency cetaceans. The mitigation zones also extend beyond or into a portion of the average ranges to TTS for sea turtles and marine mammals. Therefore, depending on the species, mitigation will help avoid or reduce all or a portion of the potential for exposure to mortality, non-auditory injury, PTS, and higher levels of TTS for the largest explosives in bin E4. Smaller explosives within bin E4 have shorter predicted impact ranges; therefore, the mitigation zones will cover a greater portion of the impact ranges for these explosives.

As described previously, the mitigation zone for this activity is based on the largest area within which it is practical for the Navy to implement mitigation. It is not practical to increase the mitigation zone because observations within the margin of increase would be unsafe and ineffective unless the Navy

allocated additional platforms to the activity to observe for biological resources. The use of additional personnel and equipment (e.g., small boats, aircraft) would be unsustainable due to increased operational costs and an exceedance of available manpower and resources for this activity. Adding aircraft to observe the mitigation zone could result in airspace conflicts with the event participants. This would either require the aircraft conducting the activity to modify their flight plans (which would reduce activity realism) or force the observing aircraft to position itself a safe distance away from the activity area (which would decrease observation effectiveness). Adding vessels to observe the mitigation zone would increase safety risks due to the presence observation vessels within the vicinity of detonations.

Increasing the mitigation zone size would result in a larger area over which firing would need to be ceased in response to a sighting, and therefore would likely increase the number of times detonations would be ceased and would extend the length of the activity. These impacts would significantly diminish realism in a way that would prevent the activity from meeting its intended objectives. For example, Mine Neutralization – Remotely Operated Vehicle Sonar training exercises require focused situational awareness of the activity area and continuous coordination of tactics between ship, small boat, and rotary-wing aircraft crews to locate and neutralize mines. During Mine Countermeasure and Neutralization Testing events, personnel evaluate the system's ability to detect and destroy mines from an airborne mine countermeasures-capable rotary-wing aircraft in advance of delivery to the fleet for operational use. Extending the length of these activities would require aircraft to depart the activity area to refuel. If multiple refueling events were required, the length of the activity would be extended by two to five times or more. This would decrease the ability for Lookouts to safely and effectively maintain situational awareness of the activity area and would increase safety risks due to increased pilot fatigue and accelerated fatigue-life of aircraft.

These types of impacts would result in a significant loss of training or testing time (which would reduce the number of opportunities that platforms have to locate and neutralize mines and reduce the Navy's ability to validate whether mine neutralization systems perform as expected) and cause a significant delay to the training or testing schedule. Therefore, an increase in mitigation would impede the ability for the Navy to train and become proficient in using mine neutralization systems as required during military missions and combat operations, would prevent units from meeting their individual training and certification requirements (which would prevent them from deploying with the required level of readiness necessary to accomplish their missions), and would impede the ability of program managers and weapons system acquisition programs to meet testing requirements per required acquisition milestones or on an as-needed basis to meet operational requirements. Extending the length of the activities would also result in additional operational costs due to increased fuel consumption.

In summary, the operational community determined that implementing procedural mitigation for explosive mine countermeasure and neutralization activities beyond what is detailed in Table 5-10 would be incompatible with the practicality assessment criteria for safety, sustainability, and mission requirements.

5.3.3.8 Explosive Mine Neutralization Activities Involving Navy Divers

The Navy will continue to implement procedural mitigation to avoid or reduce potential impacts on marine mammals and sea turtles from explosive mine neutralization activities involving Navy divers as outlined in Table 5-11.

Table 5-11: Procedural Mitigation for Explosive Mine Neutralization Activities Involving Navy Divers

Procedural Mitigation Description
Stressor or Activity • Explosive mine neutralization activities involving Navy divers
Resource Protection Focus • Marine mammals • Sea turtles • Fish (hammerhead sharks and manta rays of any species due to the difficulty of differentiating species)
Number of Lookouts and Observation Platform • 2 Lookouts (two small boats with one Lookout each, or one Lookout on a small boat and one in a rotary-wing aircraft) when implementing the smaller mitigation zone • 4 Lookouts (two small boats with two Lookouts each), and a pilot or member of an aircrew will serve as an additional Lookout if aircraft are used during the activity, when implementing the larger mitigation zone • All divers placing the charges on mines will support the Lookouts while performing their regular duties and will report applicable sightings to their supporting small boat or Range Safety Officer. • If additional platforms are participating in the activity, personnel positioned in those assets (e.g., safety observers, evaluators) will support observing the mitigation zone for applicable biological resources while performing their regular duties.
Mitigation Requirements • Mitigation zones: – For Lookouts on small boats or aircraft: 500 yd. around the detonation site during activities under positive control – For Lookouts on small boats or aircraft: 1,000 yd. around the detonation site during activities using time-delay fuses – For divers: The underwater detonation location, which is defined as the sea space within the divers' range of visibility but no further than the mitigation zone specified for Lookouts on small boats or aircraft (500 yd. or 1,000 yd. depending on the charge type) • Prior to the initial start of the activity (e.g., when maneuvering on station for activities under positive control; 30 minutes for activities using time-delay firing devices): – Lookouts on small boats or aircraft will observe the mitigation zone for marine mammals, sea turtles, hammerhead sharks, and manta rays; if observed, the Navy will relocate or delay the start of detonations or fuse initiation. • During the activity: – Lookouts on small boats or aircraft will observe the mitigation zone for marine mammals, sea turtles, hammerhead sharks, and manta rays; if observed, the Navy will cease detonations or fuse initiation. – While performing their normal duties, divers will observe the underwater detonation location for marine mammals, sea turtles, hammerhead sharks, and manta rays. Divers will notify their supporting small boat or Range Safety Officer of marine mammal, sea turtle, hammerhead shark, and manta ray sightings at the underwater detonation location; if observed, the Navy will cease detonations or fuse initiation. – To the maximum extent practicable depending on mission requirements, safety, and environmental conditions, boats will position themselves near the mid-point of the mitigation zone radius (but outside of the detonation plume and human safety zone), will position themselves on opposite sides of the detonation location (when two boats are used), and will travel in a circular pattern around the detonation location with one Lookout observing inward toward the detonation site and the other observing outward toward the perimeter of the mitigation zone. – If used, aircraft will travel in a circular pattern around the detonation location to the maximum extent practicable. – The Navy will not set time-delay firing devices to exceed 10 minutes. • Commencement/recommencement conditions after a marine mammal, sea turtle, hammerhead shark, or manta ray sighting before or during the activity: – The Navy will allow a sighted marine mammal, sea turtle, hammerhead shark, or manta ray to leave the underwater detonation location or mitigation zone (as applicable) prior to the initial start of the activity (by delaying the start) or during the activity (by not commencing detonations or fuse initiation) until one of the following conditions has been met: (1) the animal is observed exiting the 500 yd. or 1,000 yd. mitigation zone; (2) the animal is thought to have exited the 500 yd. or 1,000 yd. mitigation zone based on a determination of its course, speed, and movement relative to the detonation site; or (3) the 500 yd. or 1,000 yd. mitigation zones (for Lookouts on small boats or aircraft) and the underwater detonation location (for divers) have been clear from any additional sightings for 10 minutes during activities under positive control with aircraft that have fuel constraints, or 30 minutes during activities under positive control with aircraft that are not typically fuel constrained and during activities using time-delay firing devices.

Table 5-11: Procedural Mitigation for Explosive Mine Neutralization Activities Involving Navy Divers (continued)

Procedural Mitigation Description
• After completion of an activity (for 30 minutes): – Observe the vicinity of where detonations occurred; if any injured or dead marine mammals, sea turtles, hammerhead sharks, or manta rays are observed, follow established incident reporting procedures. – If additional platforms are supporting this activity (e.g., providing range clearance), these assets will assist in the visual observation of the area where detonations occurred.

Navy divers participating in these activities may be explosive ordnance disposal personnel. In the 2015 MITT Final EIS/OEIS, the mitigation zones for explosive mine neutralization activities involving Navy divers were based on net explosive weight and the associated average ranges to PTS. When developing the mitigation for this Final SEIS/OEIS, the Navy analyzed the potential for increasing the size of the marine mammal and sea turtle mitigation zones. The Navy identified an opportunity to increase the mitigation zone size for positive control charges in bin E4 or below to enhance protections of marine mammals and sea turtles to the maximum extent practicable and for consistency across activities. The mitigation zones for explosive mine neutralization activities involving the use of Navy divers are now based on the largest areas within which it is practical to implement mitigation. Additionally, during the ESA consultation process, the Navy worked collaboratively with NMFS to enhance mitigation for ESA-listed scalloped hammerhead sharks and to develop new mitigation to avoid or reduce potential impacts on ESA-listed giant manta rays. The post-activity observations are largely a continuation from the 2015 MITT Final EIS/OEIS, with a new requirement to observe for manta rays. These post-activity observations will help the Navy determine if any resources were injured during the activity. The Navy will follow the incident reporting procedures outlined in Section 5.1.2.2.3 (Incident Reports) if an incident is detected at any time during the event, including during the post-activity observations.

The Navy is clarifying in the table that it will require observation of the mitigation zone prior to the initial start of the activity to ensure the area is clear of applicable biological resources. The Navy has always verified that the mitigation zone is visually clear prior to conducting explosive activities and is more clearly capturing this current practice in the mitigation measures for this activity. The Navy is adding a requirement that additional platforms already participating in the activity will support observing the mitigation zone before, during, and after the activity while performing their regular duties. When available, having additional personnel support observations of the mitigation zone will help increase the likelihood of detecting biological resources.

The charges used during explosive mine neutralization activities involving Navy divers are either positively controlled or initiated using a time-delay fuse. Positive control means the detonation is controlled by the personnel conducting the activity and is not authorized until the area is clear at the time of detonation. Time-delay means the detonation is fused with a specified time-delay by the personnel conducting the activity and is not authorized until the area is clear at the time the fuse is initiated but cannot be terminated once the fuse is initiated due to human safety concerns.

For activities using a time-delay fuse (which have a maximum charge size of 20 lb. net explosive weight), there is a remote chance that animals could swim into the mitigation zone after the fuse has been initiated. The Navy established a mitigation measure to set time-delay firing devices not to exceed 10 minutes to limit the potential time that animals have to swim into the mitigation zone after fuse initiation. During activities under positive control, the Navy can cease detonations at any time in

response to a sighting of a marine mammal or sea turtle. For this reason, all activities using a time-delay fuse will implement the 1,000 yd. mitigation zone, while activities that are under positive control will implement the 500 yd. mitigation zone.

For the 500 yd. mitigation zone, the small observation area and proximity to observation platforms will result in a high likelihood that Lookouts will be able to detect marine mammals and sea turtles throughout the mitigation zone. For the 1,000 yd. mitigation zone, the use of two additional Lookouts increases the likelihood that Lookouts will be able to detect marine mammals and sea turtles across the larger observation area. Due to their low vantage point on the water, Lookouts in small boats will be more likely to detect large visual cues (e.g., whale blows or large pods of dolphins) or the splashes of individual marine mammals than cryptic marine mammal species and sea turtles near the perimeter of the 1,000 yd. mitigation zone. When rotary-wing aircraft are used, Lookouts positioned in an aircraft will have a good vantage point for observing out to the perimeter of the 500 yd. and 1,000 yd. mitigation zones. The additional mitigation within the Mariana Islands Range Complex will help the Navy avoid or reduce potential impacts on ESA-listed scalloped hammerhead sharks and giant manta rays.

Bin E6 (e.g., 20 lb. net explosive weight) has the longest predicted impact ranges for the time-delay explosives that apply to the 1,000 yd. mitigation zone. Bin E6 also has the longest predicted impact ranges for the positive control explosives that apply to the 500 yd. mitigation zone. The 1,000 yd. and 500 yd. mitigation zones extend beyond the respective ranges to 50 percent non-auditory injury and 50 percent mortality for sea turtles and marine mammals. For time-delay charges, the 1,000 yd. mitigation zone extends beyond the average ranges to PTS for sea turtles, mid-frequency cetaceans, and low-frequency cetaceans, and into a portion of the average range to PTS for high-frequency cetaceans. For positive control charges, the 500 yd. mitigation zone extends beyond the average ranges to PTS for sea turtles and mid-frequency cetaceans, and into a portion of the average ranges to PTS for high-frequency cetaceans and low-frequency cetaceans. The mitigation zones also extend beyond or into a portion of the average ranges to TTS for sea turtles and marine mammals. Therefore, depending on the species, mitigation will help avoid or reduce all or a portion of the potential for exposure to mortality, non-auditory injury, PTS, and higher levels of TTS for the largest explosives in bin E6. Smaller explosives within bin E6 and explosives in smaller source bins (e.g., E5) have shorter predicted impact ranges; therefore, the mitigation zones will cover a greater portion of the impact ranges for these explosives.

As described previously, the mitigation zones developed for this Final SEIS/OEIS are based on the largest areas within which it is practical for the Navy to implement mitigation. It is not practical to increase these mitigation zones because observations within the margin of increase would be unsafe and ineffective unless the Navy allocated additional platforms to the activity to observe for biological resources. Because mine neutralization activities involve training Navy divers in the safe handling of explosive charges, one of the mission-essential safety protocols required of all event participants, including Lookouts, is to maintain focus on the activity area to ensure safety of personnel and equipment. The typical mine neutralization activity areas coincide with the mitigation zone sizes developed for this Final SEIS/OEIS; therefore, Lookouts can safely and effectively observe the mitigation zones for biological resources while simultaneously maintaining focus on the activity areas. However, if the mitigation zone sizes increased, Lookouts would need to redirect their attention beyond the activity areas. This would not meet the safety criteria since personnel would be required to direct their attention away from mission requirements. Alternatively, the Navy would need to add personnel to serve as additional Lookouts on the existing observation platforms or allocate additional platforms to

the activity to observe for biological resources. These actions would not be safe or sustainable due to an exceedance of manpower, resource, and space restrictions for these activities.

Increasing the mitigation zone sizes would result in larger areas over which detonations would need to be ceased in response to a sighting, and therefore would likely increase the number of times detonations would be ceased. This would extend the length of the activities and cause significant safety risks for Navy divers and loss of training time. Ceasing an activity (e.g., fuse initiation) with divers in the water would have safety implications for diver air consumption and bottom time. It would also impede the ability for Navy divers to complete the training exercise with the focused endurance as required during military missions and combat operations. These impacts would significantly diminish event realism in a way that would prevent activities from meeting their intended objectives. For example, the number of opportunities that divers would have to locate and neutralize mines would be reduced. Divers would then not be able to gain skill proficiency in precise identification and evaluation of a threat mine, safe handling of explosive material during charge placement, and effective charge detonation or fuse initiation. Mine neutralization activities involving the use of Navy divers only take place during daylight hours for safety reasons; therefore, extending the length of the activity could delay the activity into the next day or next several days, which would significantly impact training schedules for all participating platforms. Therefore, an increase in mitigation would impede the ability for Navy divers to train and become proficient in mine neutralization and would prevent units from meeting their individual training and certification requirements (which would prevent them from deploying with the required level of readiness necessary to accomplish their missions).

For activities that involve aircraft, extending the length of the activity would require aircraft to depart the area to refuel. If multiple refueling events were required, the length of the activity would be extended by two to five times or more, which would decrease the ability for Lookouts to safely and effectively maintain situational awareness of the activity area and increase safety risks due to increased pilot fatigue and accelerated fatigue-life of aircraft. Extending the length of the activity would also result in additional operational costs due to increased fuel consumption.

In summary, the operational community determined that implementing procedural mitigation for explosive mine neutralization activities involving Navy divers beyond what is detailed in Table 5-11 would be incompatible with the practicality assessment criteria for safety, sustainability, and mission requirements.

5.3.3.9 Maritime Security Operations – Anti-Swimmer Grenades

The Navy will continue to implement procedural mitigation to avoid or reduce potential impacts on marine mammals and sea turtles from anti-swimmer grenades during Maritime Security Operations, as outlined in Table 5-12.

In the 2015 MITT Final EIS/OEIS, the Maritime Security Operations – Anti-Swimmer Grenade mitigation zone was based on net explosive weight and the associated average ranges to PTS. When developing the mitigation for this Final SEIS/OEIS, the Navy analyzed the potential for increasing the size of the mitigation zone. The Navy determined that the current mitigation zone is the largest area within which it is practical to implement mitigation for this activity; therefore, it will continue implementing this same mitigation zone under the Proposed Action. The Navy is clarifying in the table that it will require observation of the mitigation zone prior to the initial start of the activity to ensure the area is clear of applicable biological resources. The Navy has always verified that the mitigation zone is visually clear

prior to conducting explosive activities and is more clearly capturing this current practice in the mitigation measures for this activity.

Table 5-12: Procedural Mitigation for Maritime Security Operations – Anti-Swimmer Grenades

Procedural Mitigation Description
Stressor or Activity • Maritime Security Operations – Anti-Swimmer Grenades
Resource Protection Focus • Marine mammals • Sea turtles
Number of Lookouts and Observation Platform • 1 Lookout positioned on the small boat conducting the activity • If additional platforms are participating in the activity, personnel positioned in those assets (e.g., safety observers, evaluators) will support observing the mitigation zone for applicable biological resources while performing their regular duties.
Mitigation Requirements • Mitigation zone: – 200 yd. around the intended detonation location • Prior to the initial start of the activity (e.g., when maneuvering on station): – Observe the mitigation zone for marine mammals and sea turtles; if observed, relocate or delay the start of detonations. • During the activity: – Observe the mitigation zone for marine mammals and sea turtles; if observed, cease detonations. • Commencement/recommencement conditions after a marine mammal or sea turtle sighting before or during the activity: – The Navy will allow a sighted marine mammal or sea turtle to leave the mitigation zone prior to the initial start of the activity (by delaying the start) or during the activity (by not recommencing detonations) until one of the following conditions has been met: (1) the animal is observed exiting the mitigation zone; (2) the animal is thought to have exited the mitigation zone based on a determination of its course, speed, and movement relative to the intended detonation location; (3) the mitigation zone has been clear from any additional sightings for 30 minutes; or (4) the intended detonation location has transited a distance equal to double that of the mitigation zone size beyond the location of the last sighting. • After completion of the activity (e.g., prior to maneuvering off station): – When practical (e.g., when platforms are not constrained by fuel restrictions or mission-essential follow-on commitments), observe the vicinity of where detonations occurred; if any injured or dead marine mammals or ESA-listed species are observed, follow established incident reporting procedures. – If additional platforms are supporting this activity (e.g., providing range clearance), these assets will assist in the visual observation of the area where detonations occurred.

The Navy developed a new mitigation measure requiring the Lookout to observe the mitigation zone after completion of the activity. In accordance with the 2015 MITT Final EIS/OEIS consultation requirements, the Navy currently conducts post-activity observations for some, but not all explosive activities. In developing mitigation for this Final SEIS/OEIS, the Navy determined that it could expand this requirement to other explosive activities for enhanced consistency and to help determine if any resources were injured during explosive events, when practical. The Navy is adding a requirement that additional platforms already participating in the activity will support observing the mitigation zone before, during, and after the activity while performing their regular duties. When available, having additional personnel support observations of the mitigation zone will help increase the likelihood of detecting biological resources. The Navy will follow the incident reporting procedures outlined in Section 5.1.2.2.3 (Incident Reports) if an incident is detected at any time during the event, including during the post-activity observations. The small mitigation zone size and proximity to the observation platform result in a high likelihood that Lookouts will be able to detect marine mammals and sea turtles throughout the mitigation zone.

Explosives used during Maritime Security Operations – Anti-Swimmer Grenades exercises are in bin E2 (e.g., 0.5 lb. net explosive weight). The mitigation zone extends beyond the ranges to 50 percent non-auditory injury and 50 percent mortality for sea turtles and marine mammals. The mitigation zone extends beyond the average ranges to PTS for sea turtles, mid-frequency cetaceans, and low-frequency cetaceans, and into a portion of the average range to PTS for high-frequency cetaceans. The mitigation zone also extends beyond or into a portion of the average ranges to TTS for sea turtles and marine mammals. Therefore, mitigation will help avoid or reduce all or a portion of the potential for exposure to mortality, non-auditory injury, PTS, and higher levels of TTS for the largest explosives in bin E2.

As described previously, the mitigation zone developed for this Final SEIS/OEIS is based on the largest area within which it is practical for the Navy to implement mitigation. It is not practical to increase the mitigation zone because observations within the margin of increase would be unsafe and ineffective. Because this activity involves training crews in the safe handling of explosive hand grenades, one of the mission-essential safety protocols required of all event participants, including the Lookout, is to maintain focus on the activity area to ensure safety of personnel and equipment. The typical activity area coincides with the mitigation zone; therefore, the Lookout can safely and effectively observe the mitigation zone for biological resources while simultaneously maintaining focus on the activity area. However, if the mitigation zone size increased, the Lookout would need to redirect attention to observe beyond the activity area. This would not meet the safety criteria since personnel would be required to direct their attention away from mission requirements. Alternatively, the Navy would need to either add personnel to serve as additional Lookouts on the existing observation platform or allocate additional platforms to the activity to observe for biological resources. These actions would not be safe or sustainable due an exceedance of manpower, resource, and space restrictions for this activity.

In summary, the operational community determined that implementing procedural mitigation for Maritime Security Operations – Anti-Swimmer Grenades beyond what is detailed in Table 5-12 would be incompatible with the practicality assessment criteria for safety and sustainability.

5.3.4 Physical Disturbance and Strike Stressors

The Navy will implement procedural mitigation to avoid or reduce potential impacts on biological resources from the physical disturbance and strike stressors or activities discussed in the sections below. Section 3.4.2.4 (Physical Disturbance and Strike Stressors) and Section 3.5.2.4 (Physical Disturbance and Strike Stressors) provide a full analysis of the potential impacts of physical disturbance and strikes on marine mammals and sea turtles, respectively.

5.3.4.1 Vessel Movement

The Navy will continue to implement procedural mitigation to avoid or reduce the potential for vessel strikes of marine mammals and sea turtles, as outlined in Table 5-13.

Table 5-13: Procedural Mitigation for Vessel Movement

Procedural Mitigation Description
Stressor or Activity • Vessel movement – The mitigation will not be applied if: (1) the vessel's safety is threatened, (2) the vessel is restricted in its ability to maneuver (e.g., during launching and recovery of aircraft or landing craft, during towing activities, when mooring, etc.), (3) the vessel is submerged or operated autonomously, or (4) when impractical based on mission requirements (e.g., during Amphibious Assault and Amphibious Raid exercises).
Resource Protection Focus • Marine mammals • Sea turtles
Number of Lookouts and Observation Platform • 1 Lookout on the vessel that is underway
Mitigation Requirements • Mitigation zones: – 500 yd. around whales – 200 yd. around other marine mammals (except bow-riding dolphins) – Within the vicinity of sea turtles • During the activity: – When underway, observe the mitigation zone for marine mammals and sea turtles; if observed, maneuver to maintain distance. • Additional requirements: – Within the designated vessel traffic lane during Amphibious Assault and Amphibious Raid exercises, while underway, observe for sea turtles; if observed, cease beach approach. To allow a sighted sea turtle to leave the designated vessel traffic lanes, the Navy will not recommence the beach approach until one of the recommencement conditions has been met: (1) the animal is observed exiting the designated vessel traffic lane; (2) the animal is thought to have exited the designated vessel traffic lane based on a determination of its course, speed, and movement relative to the intended impact location; or (3) the designated vessel traffic lane has been clear from any additional sightings for 30 minutes. – If a marine mammal or sea turtle vessel strike occurs, the Navy will follow the established incident reporting procedures.

The procedural mitigation measures for vessel movement are a continuation from the 2015 MITT Final EIS/OEIS based on the largest areas within which it is practical for the Navy to implement mitigation and guidance from NMFS for vessel strike avoidance. Although the Navy is unable to position Lookouts on unmanned vessels, as a standard operating procedure, some vessels that operate autonomously have embedded sensors that aid in avoidance of large objects. The embedded sensors may help those unmanned vessels avoid vessel strikes of marine mammals.

As discussed in Section 5.3.1 (Environmental Awareness and Education), it is likely that the implementation of the Marine Species Awareness Training starting in 2007, and the additional U.S. Navy Afloat Environmental Compliance Training Series modules starting in 2014, potentially helped contribute to the lack of vessel strikes of marine mammals in the Study Area. The Navy is able to detect if a whale is struck due to the diligence of standard watch personnel and Lookouts stationed specifically to observe for marine mammals while a vessel is underway. In the unlikely event that a vessel strike of a marine mammal occurs, the Navy will notify the appropriate regulatory agency immediately or as soon as operational security considerations allow per the established incident reporting procedures described in Section 5.1.2.2.3 (Incident Reports). The Navy's incident reports include relevant information pertaining to the incident, including but not limited to vessel speed.

The small mitigation zone sizes and close proximity to the observation platform will result in a high likelihood that Lookouts will be able to detect marine mammals throughout the mitigation zones while vessels are underway. A mitigation zone size is not specified for sea turtles to allow flexibility based on vessel type and mission requirements (e.g., small boats operating in a narrow harbor). Observation for

sea turtles in the designated vessel traffic lanes during Amphibious Assault and Amphibious Raid exercises will help the Navy avoid striking sea turtles in these nearshore environments.

As described in Section 5.1.1 (Vessel Safety) of the 2015 MITT Final EIS/OEIS, Navy vessels are required to operate in accordance with applicable navigation rules. Applicable rules include the Inland Navigation Rules (33 Code of Federal Regulations 83) and International Regulations for Preventing Collisions at Sea (72 COLREGS), which were formalized in the Convention on the International Regulations for Preventing Collisions at Sea, 1972. These rules require that vessels proceed at a safe speed so proper and effective action can be taken to avoid collision and so vessels can be stopped within a distance appropriate to the prevailing circumstances and conditions. In addition to complying with navigation requirements, Navy ships transit at speeds that are optimal for fuel conservation, to maintain ship schedules, and to meet mission requirements. Vessel captains use the totality of the circumstances to ensure the vessel is traveling at appropriate speeds in accordance with navigation rules. Depending on the circumstances, this may involve adjusting speeds during periods of reduced visibility or in certain locations.

As discussed in Section 3.0.5.2.3.2 (Vessels) of the 2015 MITT Final EIS/OEIS, large Navy ships typically operate at average speeds of between 10 and 15 knots, which for reference is slower than large commercial vessels, such as container ships that steam at approximately 24 knots during normal operations (Maloni et al., 2013). Operating vessels at speeds that are not optimal for fuel conservation or mission requirements would be unsustainable due to increased time on station and increased fuel consumption. Each ship has a limited amount of time that it can be underway based on target service requirements and ship schedules. Ship schedules are driven largely by training cycles, scheduled maintenance periods, certification schedules, and deployment requirements. Because of the complex logistical considerations involved with maintaining ship schedules, the Navy does not have the flexibility to extend the amount of time that ships are underway, which would result from vessel speed restriction mitigation.

Navy vessel operators need to train to proficiently operate vessels as they would during military missions and combat operations, including being able to react to changing tactical situations and evaluate system capabilities. For example, during training activities involving flight operations from an aircraft carrier, the vessel must maintain a certain wind speed over the deck to launch or recover aircraft. Depending on wind conditions, the aircraft carrier itself must travel at a certain speed to generate the wind required to launch or recover aircraft. Implementing vessel speed restrictions would increase safety risks for Navy personnel and equipment and the public during the training event and would reduce skill proficiency in a way that would increase safety risks during military missions and combat operations. Furthermore, vessel speed restrictions would not allow the Navy to continue meeting its training requirements due to diminished realism of training exercises.

The Navy needs to test the full range of its vessel and system capabilities to ensure safety and functionality in conditions analogous to military missions and combat operations. For example, during non-explosive torpedo testing activities, the Navy must operate its vessels using speeds typical of military missions and combat operations to accurately test the functionality of its acoustic countermeasures and torpedo systems during firing. Vessel speed restrictions would not allow the Navy to continue meeting its testing program requirements due to diminished realism of testing events. Researchers, program managers, and weapons system acquisition programs would be unable to conduct accurate acoustic research to meet research objectives and effectively test vessels and vessel-deployed systems and platforms before full-scale production or delivery to the fleet. Such testing is required to

ensure functionality and accuracy in military mission and combat conditions per required acquisition milestones or on an as-needed basis to meet operational requirements.

In summary, the operational community determined that implementing procedural mitigation for vessel movements beyond what is detailed in Table 5-13 would be incompatible with the practicality assessment criteria for safety, sustainability, and mission requirements.

5.3.4.2 Towed In-Water Devices

The Navy will continue to implement procedural mitigation to avoid or reduce the potential for strike of marine mammals and sea turtles from towed in-water devices, as outlined in Table 5-14. Vessels involved in towing in-water devices will implement the mitigation described in Section 5.3.4.1 (Vessel Movement), in addition to the mitigation outlined in Table 5-14.

Table 5-14: Procedural Mitigation for Towed In-Water Devices

Procedural Mitigation Description
Stressor or Activity • Towed in-water devices – Mitigation applies to devices that are towed from a manned surface platform or manned aircraft – The mitigation will not be applied if the safety of the towing platform or in-water device is threatened
Resource Protection Focus • Marine mammals • Sea turtles
Number of Lookouts and Observation Platform • 1 Lookout positioned on the manned towing platform
Mitigation Requirements • Mitigation zones: – 250 yd. around marine mammals – Within the vicinity of sea turtles • During the activity (i.e., when towing an in-water device): – Observe the mitigation zone for marine mammals and sea turtles; if observed, maneuver to maintain distance.

The mitigation zones for towed in-water devices are a continuation from the 2015 MITT Final EIS/OEIS based on the largest area within which it is practical for the Navy to implement mitigation. The small mitigation zone size and proximity to the observation platform will result in a high likelihood that Lookouts will be able to detect marine mammals throughout the mitigation zone when manned vessels or manned aircraft are towing in-water devices. A mitigation zone size is not specified for sea turtles to allow flexibility based on towing platform type and mission requirements (e.g., small boats operating in a narrow harbor).

Mission and safety requirements determine the operational parameters (e.g., course, speed) for in-water device towing platforms. Towed in-water devices must be towed at certain speeds and water depths for stability, which are controlled in part by the towing platform's speed and directional movements. Because these devices are towed and not self-propelled, they generally have limited maneuverability and are not able to make immediate course corrections. For example, during a Mine Countermeasure – Towed Mine Neutralization activity using rotary-wing aircraft, towed devices are used to trigger mines and perform various other functions, such as detaching floating moored mines. A high degree of pilot skill is required in deploying devices, safely towing them at relatively low speeds and altitudes, and then recovering devices. The aircraft can safely alter course to shift the route of the towed device in response to a sighted marine mammal or sea turtle up to a certain extent (i.e., up to the size of the mitigation zone) while still maintaining the parameters needed for stable towing. However, the

aircraft would be unable to further alter its course to more drastically course-correct the towed device without decreasing towing stability, which would have implications for safety of personnel and equipment.

In summary, the operational community determined that implementing procedural mitigation for towed in-water devices beyond what is detailed in Table 5-14 would be incompatible with the practicality assessment criteria for safety.

5.3.4.3 Small-, Medium-, and Large-Caliber Non-Explosive Practice Munitions

The Navy will continue to implement procedural mitigation to avoid or reduce the potential for strike of marine mammals and sea turtles from small-, medium-, and large-caliber non-explosive practice munitions, as outlined in Table 5-15.

Table 5-15: Procedural Mitigation for Small-, Medium-, and Large-Caliber Non-Explosive Practice Munitions

Procedural Mitigation Description
Stressor or Activity • Gunnery activities using small-, medium-, and large-caliber non-explosive practice munitions – Mitigation applies to activities using a surface target
Resource Protection Focus • Marine mammals • Sea turtles
Number of Lookouts and Observation Platform • 1 Lookout positioned on the platform conducting the activity – Depending on the activity, the Lookout could be the same as the one described in Section 5.3.2.2 (Weapons Firing Noise)
Mitigation Requirements • Mitigation zone: – 200 yd. around the intended impact location • Prior to the initial start of the activity (e.g., when maneuvering on station): – Observe the mitigation zone for marine mammals and sea turtles; if observed, relocate or delay the start of firing. • During the activity: – Observe the mitigation zone for marine mammals and sea turtles; if observed, cease firing. • Commencement/recommencement conditions after a marine mammal or sea turtle sighting before or during the activity: – The Navy will allow a sighted marine mammal or sea turtle to leave the mitigation zone prior to the initial start of the activity (by delaying the start) or during the activity (by not recommencing firing) until one of the following conditions has been met: (1) the animal is observed exiting the mitigation zone; (2) the animal is thought to have exited the mitigation zone based on a determination of its course, speed, and movement relative to the intended impact location; (3) the mitigation zone has been clear from any additional sightings for 10 minutes for aircraft-based firing or 30 minutes for vessel-based firing; or (4) for activities using a mobile target, the intended impact location has transited a distance equal to double that of the mitigation zone size beyond the location of the last sighting.

The mitigation zone is conservatively designed to be several times larger than the impact footprint for large-caliber non-explosive practice munitions, which are the largest projectiles used for these activities. Small-caliber and medium-caliber non-explosive practice munitions have smaller impact footprints than large-caliber non-explosive practice munitions; therefore, the mitigation zone will extend even further beyond the impact footprints for these smaller projectiles.

Large-caliber gunnery activities involve vessels firing projectiles at a target located up to 6 NM down range. Small- and medium-caliber gunnery activities involve vessels or aircraft firing projectiles at targets located up to 4,000 yd. down range, although typically much closer. Lookouts will have a better likelihood of detecting marine mammals and sea turtles when observing mitigation zones around targets located close to the firing platform. When observing activities that use a target located far from the

firing platform, Lookouts will be more likely to detect large visual cues (e.g., whale blows or large pods of dolphins) than individual marine mammals, cryptic marine mammal species, and sea turtles. Positioning additional observers closer to the targets would increase safety risks because these platforms would be located in the vicinity of an intended impact location or in the path of a projectile.

5.3.4.4 Non-Explosive Missiles and Rockets

The Navy will continue to implement procedural mitigation to avoid or reduce the potential for strike of marine mammals and sea turtles from non-explosive missiles and rockets, as outlined in Table 5-16.

Table 5-16: Procedural Mitigation for Non-Explosive Missiles and Rockets

Procedural Mitigation Description
Stressor or Activity • Aircraft-deployed non-explosive missiles and rockets – Mitigation applies to activities using a surface target
Resource Protection Focus • Marine mammals • Sea turtles
Number of Lookouts and Observation Platform • 1 Lookout positioned in an aircraft
Mitigation Requirements • Mitigation zone: – 900 yd. around the intended impact location • Prior to the initial start of the activity (e.g., during a fly-over of the mitigation zone): – Observe the mitigation zone for marine mammals and sea turtles; if observed, relocate or delay the start of firing. • During the activity: – Observe the mitigation zone for marine mammals and sea turtles; if observed, cease firing. • Commencement/recommencement conditions after a marine mammal or sea turtle sighting prior to or during the activity: – The Navy will allow a sighted marine mammal or sea turtle to leave the mitigation zone prior to the initial start of the activity (by delaying the start) or during the activity (by not recommencing firing) until one of the following conditions has been met: (1) the animal is observed exiting the mitigation zone; (2) the animal is thought to have exited the mitigation zone based on a determination of its course, speed, and movement relative to the intended impact location; or (3) the mitigation zone has been clear from any additional sightings for 10 minutes when the activity involves aircraft that have fuel constraints, or 30 minutes when the activity involves aircraft that are not typically fuel constrained.

The mitigation zone for non-explosive missiles and rockets is conservatively designed to be several times larger than the impact footprint for the largest non-explosive missile used for these activities. Smaller non-explosive missiles and non-explosive rockets have smaller impact footprints than the largest non-explosive missile used for these activities; therefore, the mitigation zone will extend even further beyond the impact footprints for these smaller projectiles.

Mitigation applies to activities using non-explosive missiles or rockets fired from aircraft at targets that are typically located up to 15 NM down range, and infrequently up to 75 NM down range. There is a chance that animals could enter the mitigation zone after the aircraft conducts its close-range mitigation zone observations and before firing begins (once the aircraft has transited to its firing position). Due to the distance between the mitigation zone and the observation platform, Lookouts will have a better likelihood of detecting marine mammals and sea turtles during the close-range observations and are less likely to detect these resources once positioned at the firing location, particularly individual marine mammals, cryptic marine mammal species, and sea turtles. The mitigation only applies to aircraft-deployed missiles and rockets for the reasons discussed in Section 5.3.3.4 (Explosive Missiles and Rockets). Positioning additional observers closer to the targets would increase safety risks because

these platforms would be located in the vicinity of an intended impact location or in the path of a projectile.

5.3.4.5 Non-Explosive Bombs and Mine Shapes

The Navy will continue to implement procedural mitigation to avoid or reduce the potential for strike of marine mammals and sea turtles from non-explosive bombs and mine shapes, as outlined in Table 5-17.

Table 5-17: Procedural Mitigation for Non-Explosive Bombs and Mine Shapes

Procedural Mitigation Description
Stressor or Activity • Non-explosive bombs • Non-explosive mine shapes during mine laying activities
Resource Protection Focus • Marine mammals • Sea turtles
Number of Lookouts and Observation Platform • 1 Lookout positioned in an aircraft
Mitigation Requirements • Mitigation zone: – 1,000 yd. around the intended target • Prior to the initial start of the activity (e.g., when arriving on station): – Observe the mitigation zone for marine mammals and sea turtles; if observed, relocate or delay start of bomb deployment or mine laying. • During the activity (e.g., during approach of the target or intended minefield location): – Observe the mitigation zone for marine mammals and sea turtles; if observed, cease bomb deployment or mine laying. • Commencement/recommencement conditions after a marine mammal or sea turtle sighting prior to or during the activity: – The Navy will allow a sighted marine mammal or sea turtle to leave the mitigation zone prior to the initial start of the activity (by delaying the start) or during the activity (by not recommencing bomb deployment or mine laying) until one of the following conditions has been met: (1) the animal is observed exiting the mitigation zone; (2) the animal is thought to have exited the mitigation zone based on a determination of its course, speed, and movement relative to the intended target or minefield location; (3) the mitigation zone has been clear from any additional sightings for 10 minutes; or (4) for activities using mobile targets, the intended target has transited a distance equal to double that of the mitigation zone size beyond the location of the last sighting.

The mitigation zone for non-explosive bombs and mine shapes is conservatively designed to be several times larger than the impact footprint for the largest non-explosive bomb used for these activities. Smaller non-explosive bombs and mine shapes have smaller impact footprints than the largest non-explosive bomb used for these activities; therefore, the mitigation zone will extend even further beyond the impact footprints for these smaller military expended materials.

Activities involving non-explosive bombing and mine laying involve aircraft deploying munitions or mine shapes from a relatively steady altitude of approximately 1,500 ft. at a surface target or in an intended minefield located beneath the aircraft. Due to the mitigation zone size, proximity to the observation platform, and the good vantage point from an aircraft, Lookouts will be able to observe the entire mitigation zone during approach of the target or intended minefield location.

5.4 At-Sea Mitigation Areas to be Implemented

As a result of the Navy's biological effectiveness and operational assessments, the Navy developed mitigation areas at sea in the MITT Study Area, as summarized in the sections below. Additional details, including the complete biological effectiveness and operational assessments for each area developed for marine mammals and sea turtles, are provided in Appendix I (Geographic Mitigation Assessment).

5.4.1 Mitigation Areas for Seafloor Resources

As outlined in Table 5-18, the Navy will implement mitigation to avoid or reduce potential impacts from explosives and physical disturbance and strike stressors on submerged cultural resources (i.e., shipwrecks), sensitive seafloor resources, and any biological resources that inhabit, shelter, rest, feed, or occur in the mitigation areas. These mitigation areas are particularly important to one or more resources for a biologically important ecological function (e.g., live hard bottom habitat and artificial reefs that provide critical ecosystem functions).

The seafloor resource mitigation is a continuation from the 2015 MITT Final EIS/OEIS. Without this mitigation, explosives and physical disturbance and strike stressors could potentially impact shallow-water coral reefs, live hard bottom, artificial reefs, shipwrecks, and their associated ecosystem components during certain training and testing activities in the Study Area. Figure 5.4-1 and Figure 5.4-2 show the relevant seafloor resources and the Navy training or testing locations that overlap them. The Navy developed mitigation areas as either the anchor swing circle diameter or a 350 yd. radius around a seafloor resource, as indicated by the best available georeferenced data.

Table 5-18: Mitigation Areas for Seafloor Resources

Mitigation Area Description
Stressor or Activity • Explosives • Physical disturbance and strikes
Resource Protection Focus • Shallow-water coral reefs • Live hard bottom • Artificial reefs • Shipwrecks
Mitigation Area Requirements • **Within the anchor swing circle of shallow-water coral reefs, live hard bottom, artificial reefs, and shipwrecks:** – The Navy will not conduct precision anchoring (except at designated anchorages and nearshore training areas around Guam and within Apra Harbor, where these resources will be avoided to the maximum extent practicable). • **Within a 350 yd. radius of live hard bottom, artificial reefs, and shipwrecks:** – The Navy will not conduct explosive mine countermeasure and neutralization activities or explosive mine neutralization activities involving Navy divers (except at designated nearshore training areas, where these resources will be avoided to the maximum extent practicable). – The Navy will not place mine shapes, anchors, or mooring devices on the seafloor (except in designated locations, where these resources will be avoided to the maximum extent practicable). • **Within a 350 yd. radius of shallow-water coral reefs:** – The Navy will not conduct explosive or non-explosive small-, medium-, and large-caliber gunnery activities using a surface target; explosive or non-explosive missile and rocket activities using a surface target; explosive or non-explosive bombing and mine-laying activities; explosive or non-explosive mine countermeasure and neutralization activities; and explosive or non-explosive mine neutralization activities involving Navy divers (except at designated nearshore training areas, where these resources will be avoided to the maximum extent practicable). – The Navy will not place mine shapes, anchors, or mooring devices on the seafloor (except in designated locations, where these resources will be avoided to the maximum extent practicable).

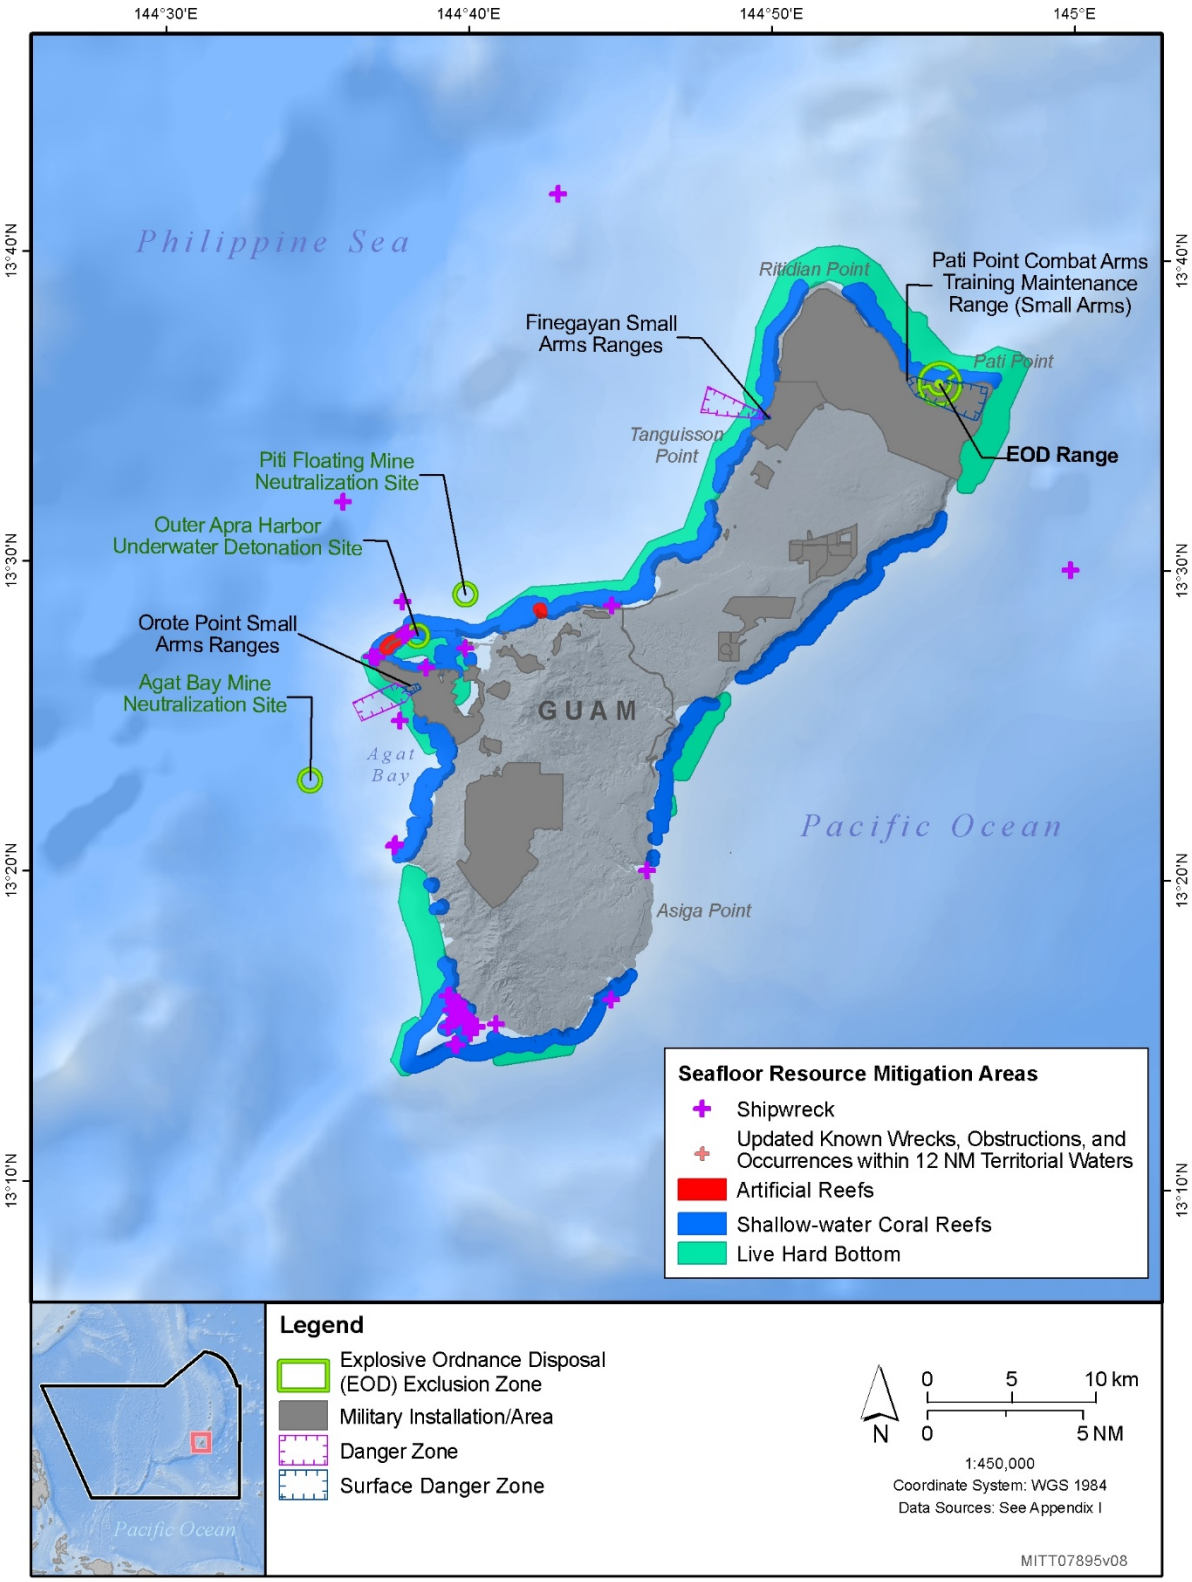

Figure 5.4-1: Seafloor Resource Mitigation Areas off Guam

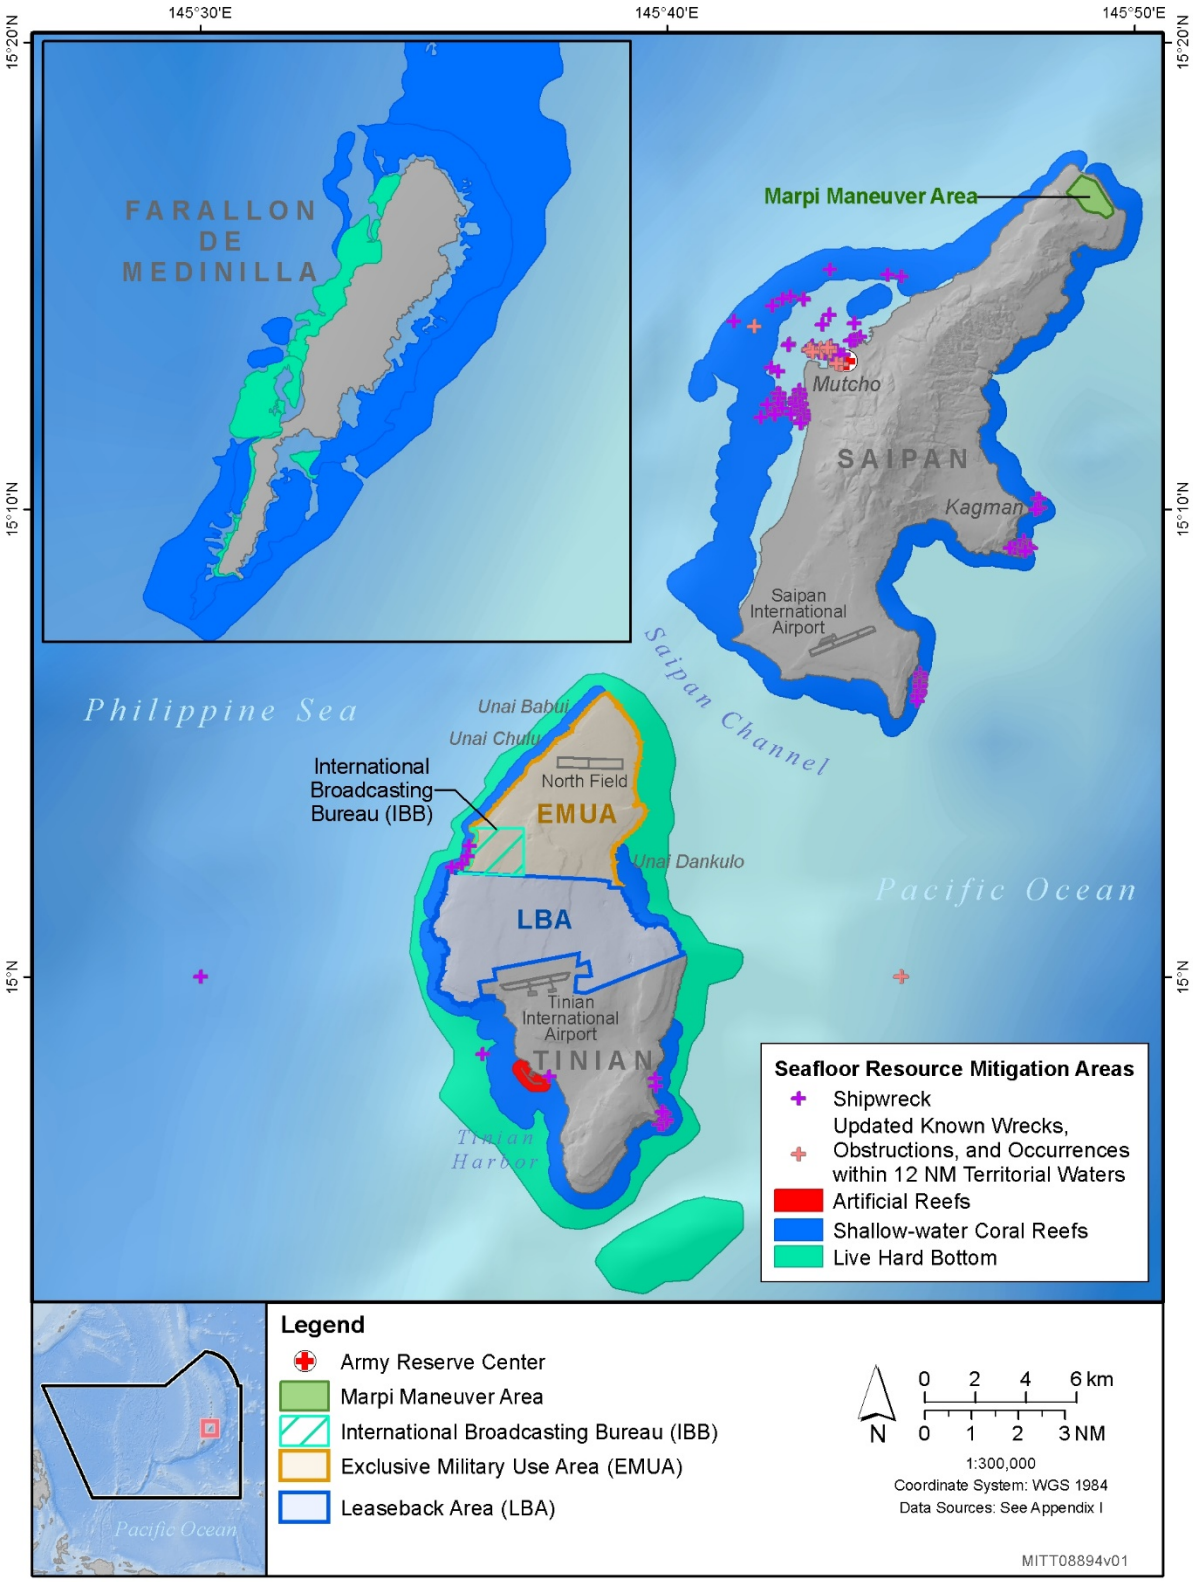

Figure 5.4-2: Seafloor Resource Mitigation Areas off Tinian, Saipan, and Farallon de Medinilla

Mitigation areas apply to georeferenced resources because the Navy requires accurate resource identification and mapping for the mitigation to be both effective as well as practical to implement. To facilitate mitigation implementation, the Navy will include maps of the best available georeferenced data for shallow-water coral reefs, artificial reefs, live hard bottom, and shipwrecks in its Protective Measures Assessment Protocol. The Navy will include data that most accurately represent the natural boundaries of seafloor resources, as described in *Building and Maintaining a Comprehensive Database and Prioritization Scheme for Overlapping Habitat Data* (U.S. Department of the Navy, 2016). Data presented in Section 3.3 (Marine Habitats), Section 3.8 (Marine Invertebrates), and Section 3.11 (Cultural Resources) will serve as the baseline of best available georeferenced data for seafloor resource mitigation areas. The Navy will also include additional seafloor resource data (such as data that the Navy has acquired access to but that is not publicly available), if applicable.

Seafloor resources fulfill important ecosystem functions. Live hard bottom habitats and artificial structures (e.g., artificial reefs, shipwrecks) provide attachment substrate for aquatic vegetation and invertebrates, such as corals, seaweed, seagrass, macroalgae, and sponges. These habitats in turn support a community of organisms, such as fish, shrimp, crabs, barnacles, worms, and sea cucumbers. Shallow-water coral reefs provide substrate, shelter, and food for hundreds of invertebrate species, sea turtles, fishes, and other biological resources. They are one of the most productive and diverse assemblages on Earth. Dive sites occur throughout nearshore areas of the Study Area where there are shipwrecks, artificial reefs, and shallow-water coral reefs, making these resources highly valuable from a socioeconomic standpoint. Similarly, submerged aquatic vegetation attached to live hardbottom or artificial reefs provides important habitat for commercially and recreationally important fish species. Historic shipwrecks are classified as archaeological resources and are an important part of maritime history.

Mitigating within the anchor swing circle will protect seafloor resources during precision anchoring activities when factoring in environmental conditions that could affect anchoring position and swing circle size, such as winds, currents, and water depth. For other activities that will implement the mitigation, a 350 yd. radius around a seafloor resource is a conservatively sized mitigation area that will provide protection well beyond the maximum expected impact footprint (e.g., crater and expelled material radius) of the explosives and non-explosive practice munitions used in the Study Area. The mitigation area size was designed to extend beyond the military expended material with the largest footprint for all Study Areas where this mitigation measure is implemented. The military expended material with the largest footprint (which is used in the Atlantic Fleet Training and Testing Study Area and Hawaii-Southern California Training and Testing Study Area, but not in the MITT Study Area) is an explosive mine with a 650 lb. net explosive weight, which has an estimated impact footprint of approximately 14,800 square ft. and an associated radius of 22.7 yd. (U.S. Department of the Navy, 2018b). The largest explosive applicable to this mitigation in the MITT Study Area has a charge size of 20 lb. net explosive weight, which has an estimated impact footprint of 135 square ft. and an associated radius of 2.19 yd. Therefore, the 350 yd. mitigation area is well beyond the maximum expected direct impact footprint for the activities listed in Table 5-18, and it further mitigates some level of indirect impact from explosive disturbances. As described in Section 3.3 (Marine Habitats), other habitat types, such as soft bottom, are expected to recover relatively quickly from potential disturbances; therefore, there would be a limited benefit of implementing this mitigation for other habitat types.

Input from the operational community indicates that the mitigation detailed in Table 5-18 is practical to implement. Implementing additional mitigation for other activities or types of seafloor resources would

not allow the Navy to continue meeting its mission requirements to successfully accomplish military readiness objectives. Expanding the mitigation to protect additional seafloor features where marine species are known to occur (e.g., soft bottom, which provides habitat for resources such as seagrass, worms, and clams) would essentially result in the Navy not conducting training and testing activities throughout a significant portion of the Study Area. This would prohibit the Navy from accessing its mission-essential activity locations. In many instances, expanding seafloor resource mitigation would also push training and testing activities farther offshore, which would have implications for safety and sustainability. Moving activities farther offshore would increase the distance from aircraft emergency landing fields, critical medical facilities, and search and rescue resources; would require excessive time on station or time away from homeport for Navy personnel; and would result in significant increases to operational costs.

In summary, the operational community determined that implementing mitigation for seafloor resources beyond what is detailed in Table 5-18 would be incompatible with the practicality assessment criteria for safety, sustainability, and mission requirements. For additional information on the biological, cultural, and socioeconomic importance of seafloor resources and their associated ecosystem components, refer to Section 3.3 (Marine Habitats), Section 3.4 (Marine Mammals), Section 3.5 (Sea Turtles), Section 3.6 (Marine Birds), Section 3.7 (Marine Vegetation), Section3.8 (Marine Invertebrates), Section 3.9 (Fish), Section 3.11 (Cultural Resources), and Section 3.12 (Socioeconomic Resources and Environmental Justice).

5.4.2 Mitigation Areas for Marine Mammals and Sea Turtles

As described in Table 5-19 and shown in Figure 5.4-3, the Navy developed mitigation areas in the MITT Study Area to avoid or reduce potential impacts on marine mammals and sea turtles. The Navy developed these mitigation areas to help avoid or reduce potential impacts from mid-frequency active sonar and explosives in areas that the best available science suggests are important to one or more species of marine mammals or sea turtles for foraging, migrating, or other biologically important life processes. As described in Appendix I (Geographic Mitigation Assessment), implementing additional mitigation in the MITT Study Area beyond what is described in Table 5-19 would be impractical due to implications for safety, sustainability, and the Navy's ability to continue meeting its mission requirements. The appendix presents details on how each area was identified and developed. Specifically, the area must be particularly important to one or more species of marine mammals or sea turtles for a biologically important life process such as foraging, migration, or reproduction. In summary, mitigation measures implemented in the following three geographic mitigation areas will help the Navy avoid or reduce potential impacts on marine mammals and sea turtles:

- **Marpi Reef Mitigation Area**. The mitigation will avoid or reduce potential impacts from hull-mounted mid-frequency active sonar and explosives on humpback whales within the mitigation area, which the best available science indicates is seasonally important reproduction habitat.
- **Chalan Kanoa Reef Mitigation Area**. The mitigation will avoid or reduce potential impacts from hull-mounted mid-frequency active sonar and explosives on humpback whales within the mitigation area, which the best available science indicates is seasonally important reproduction habitat. The mitigation will avoid or reduce potential impacts on sea turtles foraging at or near the reef.
- **Agat Bay Nearshore Mitigation Area**. The mitigation will avoid or reduce potential impacts from mid-frequency active sonar and explosives on spinner dolphins and sea turtles within the

mitigation area, which the best available science indicates is seasonally important resting habitat for spinner dolphins and foraging habitat for sea turtles.

Table 5-19: Mitigation Areas for Marine Mammals and Sea Turtles

Mitigation Area Description
Stressor or Activity • Surface Ship Hull-Mounted Mid-frequency Active Sonar (bin MF1) • In-water Explosives
Resource Protection Focus • Marine mammals • Sea turtles
Mitigation Requirements • **Marpi Reef Mitigation Area and Chalan Kanoa Reef Mitigation Area[1]** – The Navy will conduct a maximum combined total of 20 hours of surface ship hull-mounted MF1 mid-frequency active sonar during training and testing from 1 December to 30 April within the Marpi Reef Mitigation Area and Chalan Kanoa Reef Mitigation Area. The Navy will report the total hours of active sonar (all bins, by bin) used in the Marpi Reef Mitigation Area and Chalan Kanoa Reef Mitigation Area from 1 December to 30 April in its annual training and testing activity reports submitted to NMFS. Should national security present a requirement to use surface ship hull-mounted MF1 mid-frequency active sonar between 1 December to 30 April, the Navy will provide NMFS with advance notification of the activity. – The Navy will not use in-water explosives in the Marpi Reef Mitigation Area and Chalan Kanoa Reef Mitigation Area year-round. – The Navy will issue an annual seasonal awareness notification message to alert ships and aircraft operating in the Marpi Reef Mitigation Area and Chalan Kanoa Reef Mitigation Area to the possible presence of increased concentrations of humpback whales from 1 December through 30 April. To maintain safety of navigation and to avoid interactions with large whales during transits, the Navy will instruct vessels to remain vigilant to the presence of humpback whales, that when concentrated seasonally, may become vulnerable to vessel strikes. Platforms will use the information from the awareness notification messages to assist their visual observation of applicable mitigation zones during training and testing activities and to aid in the implementation of procedural mitigation. • **Agat Bay Nearshore Mitigation Area[1,2]** – The Navy will not use surface ship hull-mounted MF1 mid-frequency active sonar in the Agat Bay Nearshore Mitigation Area year-round. – The Navy will not use in-water explosives in the Agat Bay Nearshore Mitigation Area year-round.

[1] Should national security present a requirement to conduct training or testing prohibited by the mitigation requirements specified in this table, naval units will obtain permission from the appropriate designated Command authority prior to commencement of the activity. The Navy will provide NMFS with advance notification and include relevant information (e.g., sonar hours, explosives use) in its annual activity reports submitted to NMFS.

[2] The designated Command authority will base authorization on the unique characteristics of the area from a military readiness perspective, taking into account the importance of the area for spinner dolphins and sea turtles and the need to avoid adverse impacts to the maximum extent practicable. Furthermore, the Command authority conducting the activity will provide specific direction to operational units on required mitigation prior to conducting training or testing using in-water explosives in this area.

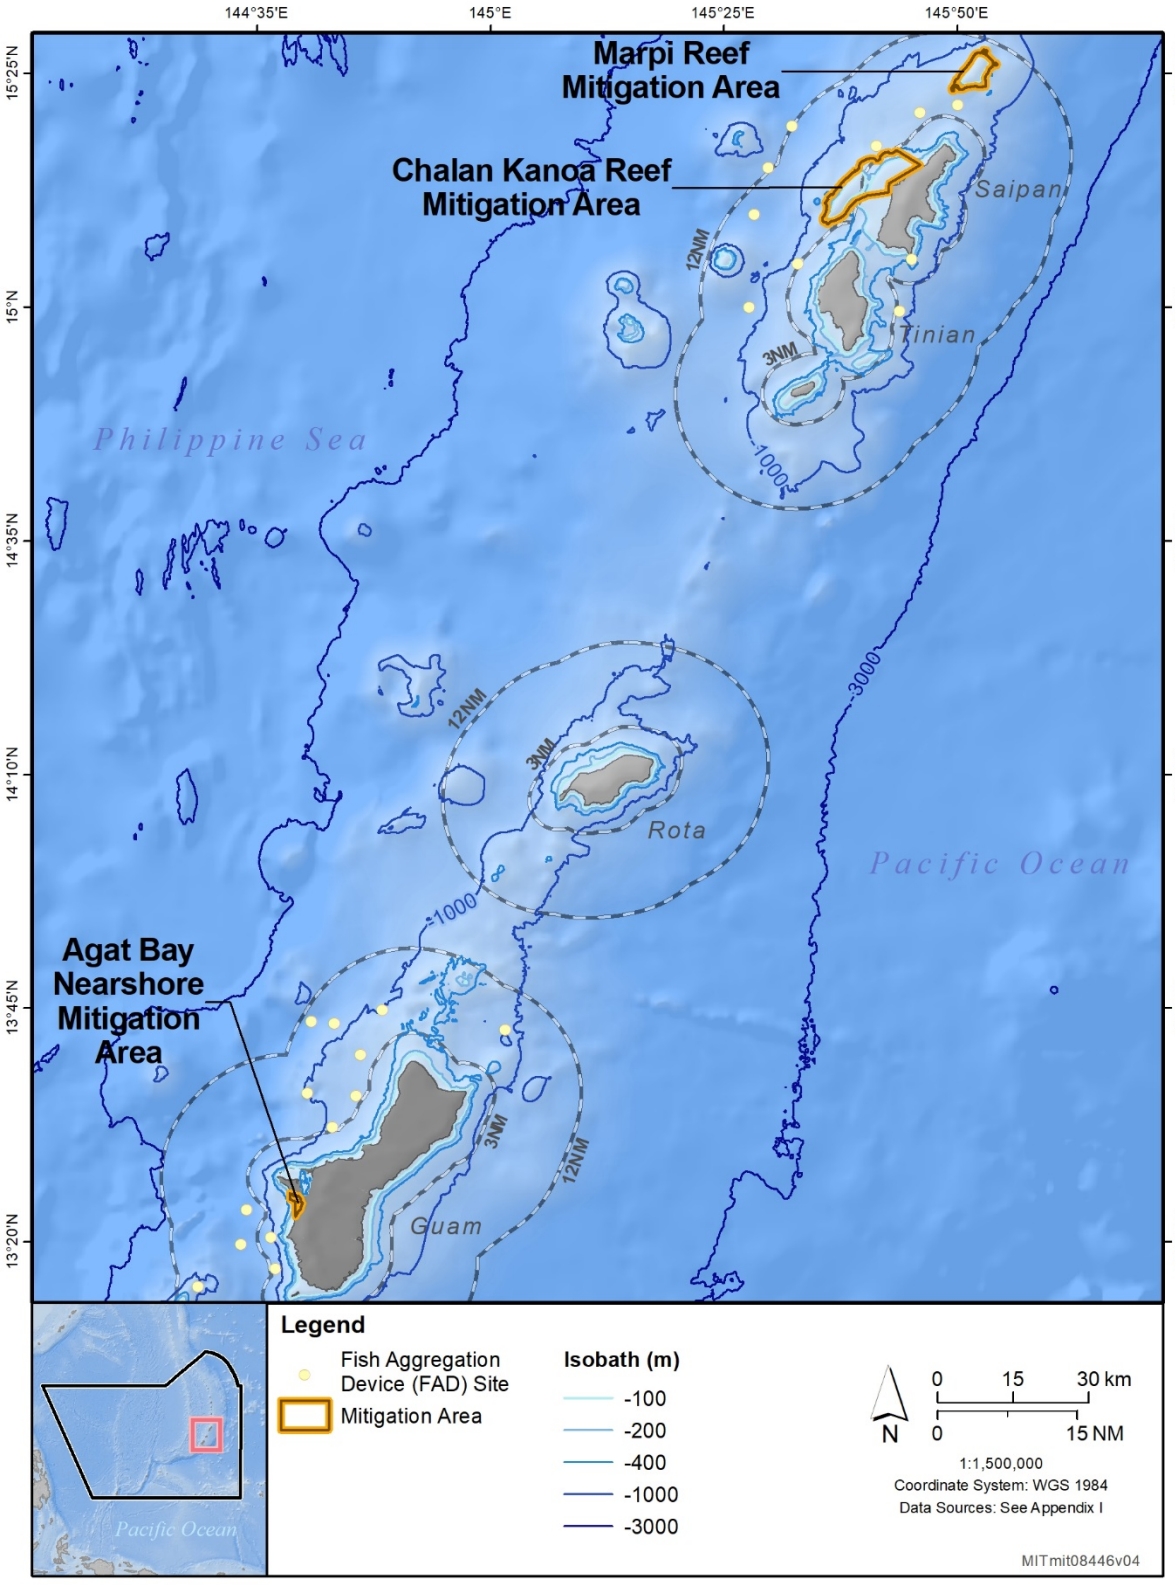

Figure 5.4-3: Marine Mammal and Sea Turtle Mitigation Areas

5.5 Terrestrial Mitigation Measures to be Implemented

The Navy will implement mitigation measures for military readiness activities conducted on FDM, which is the only terrestrial portion of the Study Area considered in this Final SEIS/OEIS. Mitigation measures for FDM are described in the section below. Information about mitigation measures the Navy implements at other terrestrial locations that are outside the scope of this Final SEIS/OEIS, such as mitigation for invasive species control and training activities conducted on the islands of Guam, Rota, Tinian, and Saipan, is presented in Chapter 5 (Standard Operating Procedures, Mitigation, and Monitoring) of the 2015 MITT Final EIS/OEIS.

5.5.1 Farallon De Medinilla

As outlined in Table 5-20, the Navy will continue to implement mitigation to avoid or reduce potential impacts on birds, bats, and sea turtles that occur on land on FDM.

Table 5-20: Farallon de Medinilla Mitigation Measures

Mitigation Area Description
Stressor or Activity • Explosives • Physical disturbance and strikes
Resource Protection Focus • Birds • Bats • Sea turtles
Mitigation Area Requirements • The Navy will not use explosive cluster weapons, scatterable munitions, fuel air explosives, incendiary munitions, depleted uranium rounds, and bombs greater than 2,000 lb. • The Navy will not target the northern Special Use Area and the narrow land bridge with explosive or non-explosive ordnance. • The Navy will not use explosive ordnance in Impact Area 1. • The Navy will only target Impact Areas 1, 2, and 3 during air-to-ground bombing, missile, and gunnery exercises. • The Navy will only fire from the west during ship-based bombardment. • Navy personnel will not be authorized on FDM without approval from Joint Region Marianas Operations. • During training activities involving aircraft dropping explosive or non-explosive ordnance on a surface target, mitigation will include visual observation immediately before and during the exercise. Firing will cease if a sea turtle is observed (on shore) in the vicinity of the intended impact location. Firing will recommence if the sea turtle is observed exiting the vicinity of the intended impact location, or if the intended impact location has been repositioned to a new location (i.e., to where the sea turtle is no longer within the vicinity of the intended impact location).

As described in Section 3.10 (Terrestrial Species and Habitats) of the 2015 MITT Final EIS/OEIS, FDM is recognized by regional ornithologists (bird specialists) as an important bird area for many species of marine birds, migrant shorebirds, and a limited number of terrestrial bird species, including the Mariana swiftlet, Mariana crow, Mariana common moorhen, Guam Micronesian kingfisher, ESA-listed Micronesian megapode, Guam rail Nightingale reed-warbler, and Rota bridled white-eye. Habitat for the Micronesian megapode on FDM primarily consists of trees, shrubs, and grasslands. The most recent survey for megapodes on FDM was completed in 2013, when Navy biologists detected 11 megapodes while surveying a limited transect within Impact Areas 1 and 2 (U.S. Department of the Navy, 2013b). FDM may also serve as Mariana fruit bat habitat for a small number of year-round residents and a stopover location for bats transiting between islands. The northern portion of the island may provide habitat for Mariana fruit bat foraging and roosting (U.S. Department of the Navy 2013a). Although the beaches on FDM are unsuitable for sea turtle nesting, green sea turtles have occasionally been observed on shore on FDM.

The Navy will continue to implement mitigation on FDM to help avoid or reduce potential impacts on ESA-listed species. Restricting the locations and type of ordnance used in the northern areas of FDM (including the Special Use Area and Impact Area 1) will help the Navy avoid or reduce potential impacts on ESA-listed Micronesian megapodes and Mariana fruit bats in the areas where they are most likely to occur for roosting and foraging. Only firing from the west during ship-based bombardment will help avoid potential impacts on rookery locations on the eastern cliff of FDM. The mitigation will also help the Navy avoid or reduce potential impacts on Micronesian megapodes and Mariana fruit bats, as well as other bird species that could be migrating or resting on FDM.

The mitigation measures on FDM are a continuation from the 2015 MITT Final EIS/OEIS based on the highest level of mitigation that is practical for the Navy to implement within this land portion of the Study Area. The Navy conducts training on FDM to ensure safety of personnel and skill proficiency in an area analogous to military mission and combat conditions. FDM is the only land training area considered in this Final SEIS/OEIS, and therefore represents the only location where certain activities, such as Naval Surface Fire Support Exercise – Land-based Target, Bombing Exercise (Air-to-Ground), Gunnery Exercise (Air-to-Ground), and Direct Action (Tactical Air Control Party) can occur as part of the Proposed Action.

Because FDM is the only terrestrial area that the Navy plans to use under the Proposed Action, it provides a unique training environment within the Study Area essential to military readiness. Therefore, further mitigation measures with regard to the level, number, type, or timing (seasonal or time of day) of training activities on FDM would be impractical due to implications for safety, sustainability, and mission requirements. For example, during a Direct Action (Tactical Air Control Party) exercise, military personnel train for controlling of combat support aircraft, providing airspace deconfliction, and terminal control for Close Air Support in conjunction with an Air-to-Ground bombing or missile exercise. Personnel may also train to employ small arms, grenades, mortars, and crew served weapons in direct action against targets on the island. This activity provides critical training on coordination of tactics between fixed-wing aircraft, rotary-wing aircraft, and small boats in an environment that cannot be replicated elsewhere in the Study Area. Reducing the number of events or further restricting the type of ordnance used during training would impede the ability for the participants to become proficient in tactical air control and using their weapons as would be required during military missions and combat operations. This would prevent units from meeting their individual training and certification requirements and deploying with the required level of readiness necessary to accomplish their missions. Additional mitigation on FDM would also have significant impacts on personnel safety due to the reduced ability to safely and effectively train personnel for tactical air control and airspace deconfliction.

5.6 Measures Considered but Eliminated

As described in Section 5.2 (Mitigation Development Process), the Navy conducted a detailed review and assessment of each potential mitigation measure individually and then all potential mitigation measures collectively to determine if, as a whole, the mitigation will be effective at avoiding or reducing potential impacts and practical to implement. The assessment included consideration of mitigation recommendations received through scoping and public comments received on the Draft SEIS/OIS for this Proposed Action, during the ESA and MMPA consultation processes, and through public comments and consultations on past environmental compliance documents applicable to the Study Area. The operational community determined that implementing procedural or terrestrial mitigation beyond what is detailed in Section 5.3 (At-Sea Procedural Mitigation to be Implemented), Section 5.4 (At-Sea Mitigation Areas to be Implemented), and Section 5.5 (Terrestrial Mitigation Measures to be Implemented) would be incompatible with the practicality assessment criteria for safety, sustainability,

and mission requirements. Information about why implementing additional mitigation measures for active sonar, explosives, active and passive acoustic monitoring devices, thermal detection systems, third-party observers, foreign navy mitigation, and reporting requirements would be impractical is provided in the sections below and in Appendix I (Geographic Mitigation Assessment).

When analyzing all potential mitigation measures collectively, the operational community determined that adopting certain mitigation measures, such as limiting active sonar to only be conducted in certain water depths, would result in the unacceptable limitation of the Navy's utilization of sea space and airspace required to effectively support training and testing of naval forces in the Study Area. Certain measures would restrict or prohibit Navy training and testing throughout most of the Study Area except in very narrow circumstances. For example, blanket limitations or restrictions on the level, number, or timing (seasonal or time of day) of training and testing activities within discrete or broad-scale areas of water (e.g., embayments and large swaths of the littorals and open ocean), or other areas vital to mission requirements would prevent the Navy from accessing its ranges, operating areas, facilities, or range support structures necessary to meet the purpose and need of the Proposed Action. As described in Section 5.2.4 (Practicality of Implementation), the Navy requires extensive sea space so that individual training and testing activities can occur at sufficient distances such that these activities do not interfere with one another, and so that Navy units can train to communicate and operate in a coordinated fashion over tens or hundreds of square miles, as required during military missions and combat operations. The Navy also needs to maintain access to sea space with the unique, challenging, and diverse environmental and oceanographic features (e.g., bathymetry, topography, surface fronts, and variations in sea surface temperature) analogous to military mission and combat conditions to achieve the highest skill proficiency and most accurate testing results possible.

Threats to national security are constantly evolving. The Navy requires the ability to adapt training and testing to meet these emerging threats. Restricting access to broad-scale areas of water would impact the ability for Navy training and testing to evolve as threats evolve. Eliminating opportunities for the Navy to train and test in a myriad of at-sea conditions would put U.S. forces at a tactical disadvantage during military missions and combat operations. This would also present a risk to national security if potential adversaries were to be alerted to the environmental conditions within which the U.S. Navy is prohibited from training and testing. Restricting large areas of ocean or other smaller areas at sea that are critical to Navy training and testing would make training and concealment much more difficult and would adversely impact the Navy's ability to perform its statutory mission.

5.6.1 Active Sonar

When assessing and developing mitigation, the Navy considered reducing active sonar training and testing hours, modifying active sonar sound sources, implementing time-of-day restrictions and restrictions during surface ducting conditions, replacing active sonar training and testing with synthetic activities (e.g., computer simulated training), and implementing active sonar ramp-up procedures. The Navy determined that it would be practical to implement certain restrictions on the use of active sonar in the Study Area, as detailed in Section 5.3.2.1 (Active Sonar) and Appendix I (Geographic Mitigation Assessment). As discussed in Chapter 2 (Description of Proposed Action and Alternatives), Section 5.2.4 (Practicality of Implementation), Appendix A (Training and Testing Activities Descriptions), and Appendix I (Geographic Mitigation Assessment), training and testing activities are planned and scheduled based on numerous factors and data inputs, such as compliance with the Optimized Fleet Response Plan. Information on why training and testing with active sonar is essential to national security is presented in Section 5.3.2.1 (Active Sonar). The Navy uses active sonar during military readiness

activities only when it is essential to training missions or testing program requirements since active sonar has the potential to alert opposing forces to the operating platform's presence. Passive sonar and other available sensors are used in concert with active sonar to the maximum extent practicable.

The Navy currently uses, and will continue to use, computer simulation to augment training and testing whenever possible. As discussed in Section 1.4.1 (Why the Navy Trains), simulators and synthetic training are critical elements that provide early skill repetition and enhance teamwork; however, they cannot replicate the complexity and stresses faced by Sailors during military missions and combat operations to which the Navy trains under the Proposed Action (e.g., anti-submarine warfare training using hull-mounted mid-frequency active sonar). Just as a pilot would not be ready to fly solo after simulator training, operational Commanders cannot allow military personnel to engage in military missions and combat operations based merely on simulator training. Similarly, in testing a system that is being developed, simulation can be used during the initial stages of development, but ultimately the system must be tested under conditions analogous to those faced during military missions and combat operations. Systems that have undergone maintenance need to be tested, and not simulated, to ensure that the system is operating correctly.

Sonar operators must train to effectively handle bottom bounce and sound passing through changing currents, eddies, and across changes in ocean temperature, pressure, salinity, depth, and in surface ducting conditions. Sonar systems must be tested in conditions analogous to where the Navy trains and operates to ensure functionality and accuracy in military mission and combat conditions. Although the majority of sonar use occurs during the day, the Navy has a nighttime training and testing requirement for some active sonar systems, and a requirement to test in a variety of locations and environmental conditions depending on the testing program objectives. Training and testing in both good visibility (e.g., daylight, favorable weather conditions) and low visibility (e.g., nighttime, inclement weather conditions) is vital because environmental differences between day and night and varying weather conditions affect sound propagation and the detection capabilities of sonar. Temperature layers that move up and down in the water column and ambient noise levels can vary significantly between night and day. This affects sound propagation and could affect how sonar systems function and are operated.

Submarines may hide in the higher ambient noise levels of shallow coastal waters and surface ducts. Surface ducting occurs when water conditions, such as temperature layers and lack of wave action, result in little sound energy penetrating beyond a narrow layer near the surface of the water. Avoiding surface ducting conditions would be impractical because ocean conditions contributing to surface ducting change frequently, and surface ducts can be of varying duration. Surface ducting can also lack uniformity and may or may not extend over a large geographic area, making it difficult to determine where to reduce power and for what periods. Submarines have long been known to take advantage of the phenomena associated with surface ducting to avoid being detected by sonar. When surface ducting occurs, active sonar becomes more useful near the surface but less useful at greater depths. As noted by the U.S. Supreme Court in *Winter v. Natural Resources Defense Council Inc.*, 555 U.S. 7 (2008), because surface ducting conditions occur relatively rarely and are unpredictable, it is especially important for the Navy to be able to train under these conditions when they occur. Training with active sonar in these conditions is a critical component of military readiness because sonar operators need to learn how sonar transmissions are altered due to surface ducting, how submarines may take advantage of them, and how to operate sonar effectively under these conditions. Reducing power, shutting down active sonar based on environmental conditions, or implementing other sonar modification techniques (e.g., sound shielding) as a mitigation would affect a Commander's ability to develop the tactical picture.

It would also prevent sonar operators from training in conditions analogous to those faced during military missions and combat operations, such as during periods of low visibility.

The Navy explicitly designs its active sonar signals to provide optimum performance at detecting underwater objects (e.g., submarines) in a variety of acoustic environments. The Navy assessed the potential for implementing active sonar signal modification as mitigation. At this time, the science on the differences in potential impacts of up or down sweeps of the sonar signal (e.g., different behavioral reactions) is extremely limited and requires further development. For example, Kastelein et al. (2012) researched the behavioral responses of a single captive harbor porpoise to varying sonar signals. Although this very limited data set suggests up or down sweeps of the sonar signal may result in different reactions by harbor porpoises in certain circumstances, this science requires further development (e.g., to determine potential reactions by other individual harbor porpoises and other marine mammal species). If future studies indicate that modifying active sonar signals (i.e., up or down sweeps) could be an effective mitigation approach, then the Navy will investigate if and how the mitigation would affect the sonar's performance. As described throughout this chapter, mitigation must meet the appropriate balance between being effective and practical to implement.

Active sonar equipment power levels are set consistent with mission requirements. Active sonar ramp-up procedures are used during seismic surveys and some foreign navy sonar activities. Ramping up involves slowly increasing sound levels over a certain length of time until the optimal source level is reached. The intent of ramping up a sound source is to alert marine mammals with a low sound level to deter them from the area and avoid higher levels of sound exposure. The best available science does not suggest that ramp-up would be an effective mitigation tool for U.S. Navy active sonar training and testing activities under the Proposed Action. Wensveen et al. (2017) found that active sonar ramp-up was not an effective method for reducing impacts on humpback whales because most whales did not display strong behavioral avoidance to the sonar signals. The study suggested that sonar ramp-up could potentially be more effective for other more behaviorally responsive species but would likely also depend on the context of exposure. For example, ramp-up would be less effective if animals have a strong motivation not to move away from their current location, such as when foraging. Dunlop et al. (2016) and von Benda-Beckmann et al. (2014) found that implementing ramp-up as a mitigation may be effective for some activities in some situations. Additionally, von Benda-Beckmann et al. (2014) found that the main factors limiting ramp-up effectiveness for a typical anti-submarine warfare activity are a high source level, a moving sonar source, and long silences between consecutive sonar transmissions. Based on the source levels, vessel speeds, and sonar transmission intervals that will be used during typical active sonar activities under the Proposed Action, the Navy has determined that ramp-up would be an ineffective mitigation measure for the active sonar activities analyzed in this Final SEIS/OEIS.

Implementing active sonar ramp-up procedures during training or testing under the Proposed Action would not be representative of military mission and combat conditions and would significantly impact training and testing realism. For example, during an anti-submarine warfare exercise using active sonar, ramp-ups have the potential to alert opponents (e.g., target submarines) to the transmitting vessel’s presence. This would defeat the purpose of the training by allowing the target submarine to detect the searching unit and take evasive measures, thereby denying the sonar operator the opportunity to learn how to locate the submarine. Similarly, testing program requirements determine test parameters to accurately determine whether a system is meeting its operational and performance requirements; therefore, implementing ramp-up during testing activities would impede the Navy’s ability to collect essential data for evaluation of a system’s capabilities.

Reducing realism in training impedes the ability for Navy Sailors to train and become proficient in using active sonar, erodes capabilities, and reduces perishable skills. These impacts would result in a significant risk to personnel safety during military missions and combat operations and would prevent units from meeting their individual training and certification requirements. Therefore, implementing additional mitigation that would reduce training realism would ultimately prevent units from deploying with the required level of readiness necessary to accomplish their missions and impede the Navy's ability to certify forces to deploy to meet national security tasking. Reducing realism in testing would impact the ability of researchers, program managers, and weapons system acquisition programs to conduct accurate acoustic research and effectively test systems and platforms (and components of these systems and platforms) before full-scale production or delivery to the fleet. These tests are required to ensure functionality and accuracy in military mission and combat conditions per required acquisition milestones or on an as-needed basis to meet operational requirements.

5.6.2 Explosives

When assessing and developing mitigation, the Navy considered reducing the number and size of explosives and limiting the locations and time of day of explosive training and testing in the Study Area. The Navy determined that it would be practical to implement certain restrictions on the use of explosives in the Study Area, as detailed in Section 5.3.3 (Explosive Stressors) and Appendix I (Geographic Mitigation Assessment). As discussed in Chapter 2 (Description of Proposed Action and Alternatives), Section 5.2.4 (Practicality of Implementation), Appendix I (Geographic Mitigation Assessment), Appendix A (Training and Testing Activities Descriptions), and Appendix I (Geographic Mitigation Assessment), the locations and timing of the training and testing activities that use explosives vary throughout the Study Area based on range scheduling, mission requirements, testing program requirements, and standard operating procedures for safety and mission success.

Activities that involve explosive ordnance are inherently different from those that involve non-explosive practice munitions. For example, critical components of an explosive Bombing Exercise Air-to-Surface include the assembly, loading, delivery, and assessment of the explosive bomb. The explosive bombing training exercise starts with ground personnel, who must practice the building and loading of explosive munitions. Training includes the safe handling of explosive material, configuring munitions to precise specifications, and the loading of munitions onto aircraft. Aircrew must then identify a target and safely deliver fused munitions, discern if the bomb was assembled correctly, and determine bomb damage assessments based on how and where the explosive detonated. An air-to-surface bombing exercise using non-explosive practice munitions can train aircrews on valuable skills to locate and accurately deliver munitions on a target; however, it cannot effectively replicate the critical components of an explosive activity in terms of assembly, loading, delivery, and assessment of an explosive bomb. Reducing the number and size of explosives or diminishing activity realism by implementing time of day or geographic restrictions for additional explosive training activities would impede the ability for Navy Sailors to train and become proficient in using explosive weapons systems (which would result in a significant risk to personnel safety during military missions and combat operations), and would ultimately prevent units from meeting their individual training and certification requirements (which would prevent them from deploying with the required level of readiness necessary to accomplish their missions) and impede the Navy's ability to certify forces to deploy to meet national security tasking.

Similar to training, the Navy is required to test its explosives to quantify the compatibility of weapons with the platform from which they will be launched or released in military missions and combat operations. Such testing requires the use of the actual explosive ordnance that will be used during

training exercises, military missions, and combat operations. Reducing the number and size of explosives or diminishing activity realism by implementing time of day or geographic restrictions for additional explosive testing events would impact the ability of researchers, program managers, and weapons system acquisition programs to effectively test systems and platforms (and components of these systems and platforms). Such testing must be conducted before full-scale production or delivery to the fleet to ensure functionality and accuracy in military mission and combat conditions per required acquisition milestones or on an as-needed basis to meet operational requirements.

5.6.3 Active and Passive Acoustic Monitoring Devices

When assessing and developing mitigation, the Navy considered using active and passive acoustic monitoring devices as procedural mitigation. During Surveillance Towed Array Sensor System low-frequency active sonar (which is not part of the Proposed Action), the Navy uses a specially designed adjunct high-frequency marine mammal monitoring active sonar known as "HF/M3" to mitigate potential impacts. HF/M3 can only be towed at slow speeds and operates like a fish finder used by commercial and recreational fishermen. Installing the HF/M3 adjunct system on the tactical sonar ships used under the Proposed Action would have implications for safety and mission requirements due to impacts on speed and maneuverability. Furthermore, installing the system would significantly increase costs associated with designing, building, installing, maintaining, and manning the equipment. The Navy will not install the HF/M3 system or other adjunct marine mammal monitoring devices as mitigation under the Proposed Action. However, Navy assets with passive acoustic monitoring capabilities that are already participating in an activity will continue to monitor for marine mammals, as described in Section 5.2.1 (At-Sea Procedural Mitigation Development) and Section 5.3 (At-Sea Procedural Mitigation to be Implemented). Significant manpower and logistical constraints make constructing and maintaining additional passive acoustic monitoring systems for each training and testing activity under the Proposed Action impractical. For example, the Navy does not have available manpower or resources to allocate additional aircraft for the purpose of deploying, monitoring, and retrieving passive acoustic monitoring equipment during a bombing exercise. All platforms participating in explosive bombing exercises (e.g., firing aircraft, safety aircraft) must focus on situational awareness of the activity area and continuous coordination between multiple training components for safety and mission success. Therefore, it is impractical for participating platforms to divert their attention to non-mission essential tasks, such as deploying sonobuoys and monitoring for acoustic detections during the event (e.g., setting up a computer station). Diverting platforms with passive acoustic monitoring capabilities to monitor training and testing events would impact their ability to meet their mission requirements and would reduce the service life of those systems.

The Navy is continuing to improve its capabilities to use range instrumentation to aid in the passive acoustic detection of marine mammals. For example, at the Southern California Offshore Range, the Pacific Missile Range Facility off Kauai, Hawaii, and the Atlantic Undersea Test and Evaluation Center in the Bahamas, the Navy can monitor instrumented ranges in real-time or through data recorded by hydrophones. The Navy has sponsored numerous studies that have produced meaningful results on marine mammal occurrence, distribution, and behavior on these ranges through the U.S. Navy's Marine Species Monitoring Program. For information on the U.S. Navy's Marine Species Monitoring Program, see Section 5.1.2.2.1 (Marine Species Research and Monitoring Programs).

Although the Navy's instrumented ranges are helping to facilitate a better understanding of the species that are present in those areas, instrumented ranges were not developed for the purpose of mitigation, and therefore do not have the capabilities to be used effectively for mitigation. To develop an estimated

position for an individual marine mammal, the animal's vocalizations must be detected on at least three hydrophones. The vocalizations must be loud enough to provide the required signal to noise ratio on those hydrophones. The hydrophones must have the required bandwidth and dynamic range to capture that signal. Detection capabilities are generally degraded under noisy conditions (such as high sea state) that affect signal to noise ratio. The ability to detect and develop an estimated position for marine mammals on the Navy's instrumented ranges depends of numerous factors, such as behavioral state (e.g., only vocalizing animals can be detected), species (e.g., species vocalize at varying rates, call types, and source levels), animal location relative to the passive acoustic receivers (hydrophones), and location on the range. The Navy's hydrophones cannot track the real-time locations of individual animals with dispersed and directional vocalizations with the level of precision needed for effective mitigation. Even marine mammals that have been vocalizing for extended periods of time have been known to stop vocalizing for hours at a time, which would prevent the Navy from obtaining or maintaining an accurate estimate of that animal's location. In addition, the Navy does not currently have the capability to perform data processing for large baleen whales in real-time. Determining if an animal is located within a mitigation zone within the timeframes required for mitigation would be prohibited by the amount of time it takes to process the data.

If a vocalizing animal is detected on only one or two hydrophones, estimating its location is not possible, and the location of the animal would be assigned generally within the detection radius around each hydrophone. The detection radius of a hydrophone is typically much larger than the mitigation zone for the activities conducted on instrumented ranges. The Navy does not have a way to verify if that vocalizing animal is located within the mitigation zone or at a location down range. Mitigating for passive acoustic detections based on unknown animal locations would essentially increase the mitigation zone sizes for each activity to that of the hydrophone detection radius. Increasing the mitigation zone sizes beyond what is described for each activity is impractical for the reasons described throughout Section 5.3 (At-Sea Procedural Mitigation to be Implemented).

In summary, although the Navy is continuing to improve its capabilities to use range instrumentation to aid in the passive acoustic detection of marine mammals, at this time it would not be effective or practical for the Navy to monitor instrumented ranges for real-time mitigation or to construct additional instrumented ranges as a tool to aid in the implementation of mitigation.

5.6.4 Thermal Detection Systems

When assessing and developing mitigation, the Navy considered using thermal detection systems and other technologies (e.g., autonomous platforms such as unmanned aerial vehicles, X-band radar) as procedural mitigation. The use of X-band radar instruments for marine mammal monitoring is a new field of study. A preliminary pilot experiment in the Mediterranean Sea indicated that X-band radar instruments, which allow for continuous observation of the sea surface within a certain range from the radar antenna, were able to detect bottlenose dolphins during optimal weather and sea state conditions (Mingozzi et al., 2020). Detections by radar were generally limited by conditions such as waves, which did not allow for the correct identification of small targets; and rain, which masked the radar signal reflection and reduced the ability to detect targets. The pilot experiment used a manual approach to observe for and validate radar detections; however, future technological developments could potentially allow for automated marine mammal observation using X-band radar (Mingozzi et al., 2020).

Thermal detection technology is designed to allow observers to detect the difference in temperature between a surfaced marine mammal (i.e., the body or blow of a whale) and the environment (i.e., the

water and air). Thermal detection systems can be effective at detecting some types of marine mammals in a limited range of marine environmental conditions. Technologies are advancing but continue to be limited by their: (1) reduced performance in certain environmental conditions, (2) ability to detect certain animal characteristics and behaviors, (3) low sensor resolution and narrow fields of view, and (4) high cost and low lifecycle (Boebel, 2017; Zitterbart et al., 2013). Current thermal detection systems have proven more effective at perceiving thermal anomalies as distance to the observer decreases (Zitterbart et al., 2020), and at detecting large whale blows than the bodies of small animals, particularly at a distance (Zitterbart et al., 2013). Zitterbart et al. (2020) found that certain cues, such as those caused by the displacement of relatively large amounts of water (e.g., whale breaches) were less affected by distance than other cues (e.g., whale blows) that showed a linear decay related to the effects of wind on thermal perceptibility. The study also found that the maximum thermal perceptibility distance ranged from <1 to 10 kilometers, depending on factors such as cue type, species, and observation location.

The effectiveness of current technologies has not been demonstrated for small marine mammals. Thermal detection systems exhibit varying degrees of false positive detections (i.e., incorrect notifications) due in part to their low sensor resolution and reduced performance in certain environmental conditions. False positive detections may incorrectly identify other features (e.g., birds, waves, boats) as marine mammals. Zitterbart et al. (2013) reported a false positive rate approaching one incorrect notification per four minutes of observation. Zitterbart et al. (2020) reported maximum false positive rates of greater than 30 or 50 per hour, depending on observation location.

Thermal detection systems are generally thought to be most effective in detecting large, short-diving marine mammals in cold environments where there is a large temperature differential between an animal's temperature and the environment (Verfuss et al., 2018). Two studies that examined the effectiveness of thermal detection systems for marine mammal observations are Zitterbart et al. (2013), which tested a thermal detection system and automatic algorithm in polar waters between 34 and 50 degrees Fahrenheit, and a Navy-funded study in subtropical and tropical waters. Zitterbart et al. (2013) found that current technologies have limitations regarding temperature and survey conditions (e.g., rain, fog, sea state, glare, ambient brightness), for which further effectiveness studies are required. The Office of Naval Research Marine Mammals and Biology program funded a project (2013–2018) to test the thermal limits of infrared-based automatic whale detection technology. That project focused on capturing whale spouts at two different locations featuring subtropical and tropical water temperatures, optimizing detector/classifier performance on the collected data, and testing system performance by comparing system detections with concurrent visual observations. Results indicated that thermal detection systems in subtropical and tropical waters can be a valuable addition to marine mammal surveys within a certain distance from the observation platform (e.g., during seismic surveys, vessel movements), but they have challenges associated with false positive detections of waves and birds (Boebel, 2017).

The Navy has also been investigating the use of thermal detection systems with automated marine mammal detection algorithms for future mitigation during training and testing, including on autonomous platforms. For example, the Defense Advanced Research Projects Agency funded six initial studies to test and evaluate infrared-based thermal detection technologies and algorithms to automatically detect marine mammals on an unmanned surface vehicle. Based on the outcome of these initial studies, the Navy is pursuing additional follow-on research efforts.

Thermal detection systems are currently used by some specialized U.S. Air Force aircraft for marine mammal mitigation. These systems are specifically designed for and integrated into Air Force aircraft and cannot be added to Navy aircraft. Only certain Navy aircraft have specialized infrared capabilities, and these capabilities are only for fine-scale targeting within a narrow field of view. The only thermal imagery sensors aboard Navy surface ships are associated with specific weapons systems, and these sensors are not available on all vessels. These sensors are typically used only in select training events, have a limited lifespan before requiring expensive replacement, and are not optimized for marine mammal observations within the Navy's mitigation zones. For example, as described in Section 5.3.3.3 (Explosive Medium-Caliber and Large-Caliber Projectiles), Lookouts are required to observe a 1,000 yd. mitigation zone around the intended impact location during explosive large-caliber gunnery activities. In addition to observing for marine mammals, one of the activity's mission-essential requirements is for event participants, including Lookouts, to maintain focus on the mitigation zone to ensure the safety of Navy personnel and equipment and the public. Lookouts would not be able to observe the 1,000 yd. mitigation zone using the Navy's thermal imagery sensors due to their narrow fields of view and technological design specific to fine-scale targeting. Such observations would be ineffective for marine mammals and would prevent Lookouts from effectively maintaining focus on the activity area and implementing mission-essential safety protocols.

The effectiveness of even the most advanced commercially available thermal detection systems with technological designs specific to marine mammal observations is highly dependent on environmental conditions, animal characteristics, and animal behaviors (Zitterbart et al., 2013). Considering the range of environmental conditions and diversity of marine mammal species found throughout the Study Area, the use of thermal detection systems would be less effective than the traditional techniques currently employed by the Navy, such as naked-eye scanning, hand-held binoculars, and high-powered binoculars mounted on a ship deck. Furthermore, high false positive rates of thermal detection systems could result in the Navy implementing mitigation for features incorrectly identified as marine mammals. Increasing the instances of mitigation implementation based on incorrectly identified features would have significant impacts on the ability for training and testing activities to accomplish their intended objectives, without providing any mitigation benefit to the species. In addition, thermal detection systems are designed to detect marine mammals and do not have the capability to detect other resources for which the Navy is required to implement mitigation. Requiring Lookouts to use thermal detection systems would prevent them from detecting and mitigating for sea turtles and other biological resources (e.g., jellyfish aggregations).

Verfuss et al. (2018) determined that based on the science of current thermal detection system technologies, the combined performance of two or more observation methods would improve detection probability for real-time monitoring of marine mammals. Similarly, during a study conducted offshore Atlantic Canada, Smith et al. (2020) found that overall marine mammal detection rates increased when complementary methods (marine mammal observers, infrared cameras, and passive acoustic monitoring) were used. A combination of techniques balances the benefits and limitations of each method, particularly in conditions such as high sea state and low visibility. As discussed in Section 5.3 (At-Sea Procedural Mitigation to be Implemented), the Navy's procedural mitigation measures include the maximum number of Lookouts the Navy can assign to each activity based on available manpower and resources, combined with the use of passive acoustic monitoring when those assets are already participating in an activity. It would be impractical to add personnel to serve as additional Lookouts for the sole purpose of thermal detection system use under the Proposed Action because the Navy does not

have available manpower to add Lookouts to use thermal detection systems in tandem with existing Lookouts who are using traditional observation techniques.

In summary, thermal detection systems have not been sufficiently studied both in terms of their effectiveness within the environmental conditions found in the Study Area and their compatibility with Navy training and testing. The Navy plans to continue researching thermal detection systems to determine their effectiveness and compatibility with Navy applications. If the technology matures to the state where thermal detection is determined to be an effective mitigation tool during training and testing, the Navy will assess the practicality of using the technology during training and testing events and retrofitting its observation platforms with thermal detection devices. The assessment will include an evaluation of the budget and acquisition process (including costs associated with designing, building, installing, maintaining, and manning equipment that is expensive and has a relatively short lifecycle before key system components need replacing); logistical and physical considerations for device installment, repair, and replacement (e.g., conducting engineering studies to ensure there is no electronic or power interference with existing shipboard systems); manpower and resource considerations for training personnel to effectively operate the equipment; and considerations of potential security and classification issues. New system integration on Navy assets can entail up to 5–10 years of effort to account for acquisition, engineering studies, and development and execution of systems training. The Navy will provide information to NMFS about the status and findings of Navy-funded thermal detection studies and any associated practicality assessments at the annual adaptive management meetings. Information about the Navy's adaptive management program is included in Section 5.1.2.2.1.1 (Adaptive Management).

5.6.5 Third-Party Observers

When assessing and developing mitigation, the Navy considered using third-party observers during training and testing to aid in the implementation of procedural mitigation. The use of third-party observers to conduct pre- or post-activity biological resource observations would be an ineffective mitigation because marine mammals would likely move into or out of the activity area, and mitigation must be implemented at the time the activity is taking place.

There are significant manpower and logistical constraints that make using third-party observers for every training and testing activity under the Proposed Action impractical. Training and testing activities often occur simultaneously and in various regions throughout the Study Area, some of which last for days or weeks at a time. Having third-party observers embark on Navy vessels or aircraft would result in safety and security clearance issues. Training and testing event planning includes careful consideration of capacity limitations when placing personnel on participating aircraft and vessels. The Navy is unable to add third-party observers on a ship or substitute a Navy Lookout with a third-party observer without causing a berthing shortage or exceedance of other space limitations, or impacting the ability for Lookouts to complete their other mission-essential duties. The use of third-party observers also presents national security concerns due to the requirement to provide advance notification of specific times and locations of Navy platform movements and activities (e.g., vessels using active sonar).

Reliance on the availability of third-party personnel for mitigation would be impractical because training and testing activity timetables oftentimes cannot be precisely fixed and are instead based on the free-flow development of tactical situations. Waiting for third-party aircraft or vessels to complete surveys, refuel, or transit on station would extend the length of the activity in a way that would diminish realism and delay training and testing schedules. Hiring third-party civilian vessels or aircraft to observe Navy training and testing activities would also be unsustainable due to the significant associated costs.

Because many training and testing activities take place offshore, the amount of time observers would spend on station would be limited due to aircraft fuel restrictions. Fuel restrictions and distance from shore would increase safety risks should mechanical problems arise. The presence of civilian aircraft or vessels in the vicinity of training and testing activities would present increased safety risks due to airspace conflicts and proximity to explosives.

5.6.6 Foreign Navy Mitigation

When assessing and developing mitigation, the Navy considered adopting the mitigation measures implemented by foreign navies. Mitigation measures are carefully developed for and assessed by each individual navy based on the potential impacts of their activities on the biological resources that live in their Study Areas, and the practicality of mitigation implementation based on their training mission and testing program requirements and the resources available for mitigation. The U.S. Navy's readiness considerations differ from those of foreign navies based on each navy's strategic reach, global mission, country-specific legal requirements, and geographic considerations. Most non-U.S. navies do not possess an integrated strike group and do not have integrated training requirements. The U.S. Navy's training is built around the integrated warfare concept and is based on the U.S. Navy's capabilities, the threats faced, the operating environment, and the overall mission. For this reason, not all measures developed for foreign navies would be effective at reducing impacts of U.S. Navy training or testing, or practical to implement by the U.S. Navy (and vice versa). For example, some navies implement active sonar ramp-up as mitigation for marine mammals; however, as described in Section 5.6.1 (Active Sonar), the U.S. Navy determined that active sonar ramp-up would be an ineffective mitigation measure for training and testing activities under the Proposed Action and would be impractical to implement because it would significantly impact training and testing realism.

The U.S. Navy will implement mitigation measures that have been determined to be effective at avoiding or reducing impacts from the Proposed Action and practical to implement by the U.S. Navy. Many of these measures are the same as, or comparable to, those implemented by foreign navies. For example, most navies implement some form of procedural mitigation to cease certain activities if a marine mammal is observed in a mitigation zone (Dolman et al., 2009). Some navies also implement geographic mitigation to restrict activities within particularly important marine mammal breeding, feeding, or migration habitats. The U.S. Navy will implement several mitigation measures and environmental compliance initiatives that are not implemented by foreign navies. For example, as discussed in Section 5.1.2.2 (Monitoring, Research, and Reporting Initiatives), the U.S. Navy will continue to sponsor scientific monitoring and research and comply with stringent reporting requirements.

5.6.7 Reporting Requirements

When assessing and developing mitigation, the Navy considered increasing its reporting requirements, such as additional reporting of vessel speeds and marine species observations. As discussed in Section 5.1.2.2 (Monitoring, Research, and Reporting Initiatives), the Navy developed its reporting requirements in conjunction with NMFS to be consistent with mission requirements and balance the usefulness of the information to be collected with the practicality of collecting it. The Navy's training and testing activity reports and incident reports are designed to verify implementation of mitigation; comply with current permits, authorizations, and consultation requirements; and improve future environmental analyses. The Navy reports to NMFS if mitigation was implemented during sinking exercises (e.g., number of times explosive detonations were delayed due to marine mammal sightings). For major training exercises, the Navy's annual training and testing activity reports include information on each individual marine

mammal sighting related to mitigation implementation. In the unlikely event that a vessel strike of a marine mammal should occur, the Navy would provide NMFS with relevant information pertaining to the incident, including but not limited to vessel speed.

Additional reporting would be ineffective as mitigation because it would not result in modifications to training or testing activities or further avoidance or reductions of potential impacts. For example, additional reporting of vessel speed data would not result in modifications to vessel speeds (e.g., speed restrictions) or reduce the already low potential for vessel strikes of marine mammals for the reasons described in Section 5.3.4.1 (Vessel Movement). Lookouts are not trained to make species-specific identification and would not be able to provide detailed scientific data if more detailed marine species observation reports were to be required. Furthermore, the Navy does not currently maintain a record management system to collect, archive, analyze, and report every marine species observation or all vessel speed data for every training and testing activity and all vessel movements. For example, the speed of Navy vessels can fluctuate an unlimited number of times during training and testing events. Developing and implementing a record management system of this magnitude would be unduly cost prohibitive and place a significant administrative burden on vessel operators and activity participants. Burdening operational Commanders, vessel operators, and event participations with requirements to complete additional administrative reporting would distract them from preparing a ready force and focusing on mission-essential tasks. Additional reporting requirements would draw event participants' attention away from the complex tactical tasks they are primarily obligated to perform, such as driving a warship or engaging in a gunnery event, which would adversely impact Navy personnel safety, public safety, and the effectiveness of training or testing.

5.7 Mitigation Summary

Table 5-21, Table 5-22, and Table 5-23 summarize the mitigation measures the Navy will implement under Alternative 1 or Alternative 2 of the Proposed Action. For detailed mitigation requirements, see Section 5.3 (At-Sea Procedural Mitigation to be Implemented), Section 5.4 (At-Sea Mitigation Areas to be Implemented), Section 5.5 (Terrestrial Mitigation Measures to be Implemented), and Appendix I (Geographic Mitigation Assessment).

Table 5-21: Summary of At-Sea Procedural Mitigation

Stressor or Activity	*Mitigation Zone Sizes and Other Requirements*	*Protection Focus*
Environmental Awareness and Education	• Afloat Environmental Compliance Training program for applicable personnel	Marine mammals, Sea turtles
Active Sonar	• Depending on sonar source: • 1,000 yards (yd.) power down, 500 yd. power down, and 200 yd. shut down • 200 yd. shut down	Marine mammals, Sea turtles
Weapons Firing Noise	• 30° on either side of the firing line out to 70 yd.	Marine mammals, Sea turtles
Explosive Sonobuoys	• 600 yd.	Marine mammals, Sea turtles
Explosive Torpedoes	• 2,100 yd.	Marine mammals, Sea turtles
Explosive Medium-Caliber and Large-Caliber Projectiles	• 1,000 yd. (large-caliber projectiles) • 600 yd. (medium-caliber projectiles during surface-to-surface activities) • 200 yd. (medium-caliber projectiles during air-to-surface activities)	Marine mammals, Sea turtles
Explosive Missiles and Rockets	• 2,000 yd. (21–500 pounds [lb.] net explosive weight) • 900 yd. (0.6–20 lb. net explosive weight)	Marine mammals, Sea turtles
Explosive Bombs	• 2,500 yd.	Marine mammals, Sea turtles
Sinking Exercises	• 2.5 nautical miles	Marine mammals, Sea turtles
Explosive Mine Countermeasure and Neutralization Activities	• 600 yd.	Marine mammals, Sea turtles
Explosive Mine Neutralization Activities Involving Navy Divers	• 1,000 yd. (charges using time-delay fuses) • 500 yd. (positive control charges) • Underwater detonation location (for divers)	Marine mammals, Sea turtles, Fish (hammerhead sharks, manta rays)
Maritime Security Operations – Anti-Swimmer Grenades	• 200 yd.	Marine mammals, Sea turtles
Vessel Movement	• 500 yd. (whales) • 200 yd. (other marine mammals) • Vicinity (sea turtles) • Cease beach approach during Amphibious Assault and Amphibious Raid exercises (sea turtles)	Marine mammals, Sea turtles
Towed In-Water Devices	• 250 yd. (marine mammals) • Vicinity (sea turtles)	Marine mammals, Sea turtles
Small-, Medium-, and Large-Caliber Non-Explosive Practice Munitions	• 200 yd.	Marine mammals, Sea turtles
Non-Explosive Missiles and Rockets	• 900 yd.	Marine mammals, Sea turtles
Non-Explosive Bombs and Mine Shapes	• 1,000 yd.	Marine mammals, Sea turtles

Table 5-22: Summary of At-Sea Mitigation Areas

Summary of Mitigation Requirements
Mitigation Areas for Seafloor Resources
• **Shallow-water coral reefs:** The Navy will not conduct precision anchoring, explosive mine countermeasure and neutralization activities, explosive mine neutralization activities involving Navy divers, explosive or non-explosive small-, medium-, and large-caliber gunnery activities using a surface target, explosive or non-explosive missile and rocket activities using a surface target, or explosive or non-explosive bombing or mine laying activities. The Navy will not place mine shapes, anchors, or mooring devices on the seafloor. Mitigation applies throughout the Study Area except in designated locations, where these resources will be avoided to the maximum extent practicable. • **Live hard bottom, artificial reefs, and shipwrecks:** The Navy will not conduct precision anchoring, explosive mine countermeasure and neutralization activities, or explosive mine neutralization activities involving Navy divers. The Navy will not place mine shapes, anchors, or mooring devices on the seafloor. Mitigation applies throughout the Study Area except in designated locations, where these resources will be avoided to the maximum extent practicable.
Mitigation Areas for Marine Mammals and Sea Turtles
• **Marpi Reef Mitigation Area and Chalan Kanoa Reef Mitigation Area[1]** – The Navy will conduct a maximum combined total of 20 hours of surface ship hull-mounted MF1 mid-frequency active sonar during training and testing from 1 December to 30 April within the Marpi Reef Mitigation Area and Chalan Kanoa Reef Mitigation Area. The Navy will report the total hours of active sonar (all bins, by bin) used in the Marpi Reef Mitigation Area and Chalan Kanoa Reef Mitigation Area from 1 December to 30 April in its annual training and testing activity reports submitted to NMFS. Should national security present a requirement to use surface ship hull-mounted MF1 mid-frequency active sonar between 1 December to 30 April, the Navy will provide NMFS with advance notification of the activity. – The Navy will not use in-water explosives in the Marpi Reef Mitigation Area and Chalan Kanoa Reef Mitigation Area year-round. – The Navy will issue an annual seasonal awareness notification message to alert ships and aircraft operating in the Marpi Reef Mitigation Area and Chalan Kanoa Reef Mitigation Area to the possible presence of increased concentrations of humpback whales from 1 December through 30 April. To maintain safety of navigation and to avoid interactions with large whales during transits, the Navy will instruct vessels to remain vigilant to the presence of humpback whales, that when concentrated seasonally, may become vulnerable to vessel strikes. Platforms will use the information from the awareness notification messages to assist their visual observation of applicable mitigation zones during training and testing activities and to aid in the implementation of procedural mitigation. • **Agat Bay Nearshore Mitigation Area[1,2]** – The Navy will not use surface ship hull-mounted MF1 mid-frequency active sonar in the Agat Bay Nearshore Mitigation Area year-round. – The Navy will not use in-water explosives in the Agat Bay Nearshore Mitigation Area year-round.

[1] Should national security present a requirement to conduct training or testing prohibited by the mitigation requirements specified in this table, naval units will obtain permission from the appropriate designated Command authority prior to commencement of the activity. The Navy will provide NMFS with advance notification and include relevant information (e.g., sonar hours, explosives use) in its annual activity reports submitted to NMFS.

[2] The designated Command authority will base authorization on the unique characteristics of the area from a military readiness perspective, taking into account the importance of the area for spinner dolphins and sea turtles and the need to avoid adverse impacts to the maximum extent practicable. Furthermore, the Command authority conducting the activity will provide specific direction to operational units on required mitigation prior to conducting training or testing using in-water explosives in this area.

Table 5-23: Summary of Terrestrial Mitigation

Summary of Mitigation Requirements
Terrestrial Mitigation Measures on Farallon de Medinilla for Birds, Bats, and Sea Turtles
• The Navy will not use explosive cluster weapons, scatterable munitions, fuel air explosives, incendiary munitions, depleted uranium rounds, and bombs greater than 2,000 lb. • The Navy will not target the northern Special Use Area and the narrow land bridge with explosive or non-explosive ordnance. • The Navy will not use explosive ordnance in Impact Area 1. • The Navy will only target Impact Areas 1, 2, and 3 during air-to-ground bombing, missile, and gunnery exercises. • The Navy will only fire from the west during ship-based bombardment. • Navy personnel will not be authorized on FDM without approval from Joint Region Marianas Operations. • During training activities involving aircraft dropping explosive or non-explosive ordnance on a surface target, mitigation will include visual observation immediately before and during the exercise. Firing will cease if a sea turtle is observed (on shore) in the vicinity of the intended impact location. Firing will recommence if the sea turtle is observed exiting the vicinity of the intended impact location, or if the intended impact location has been repositioned to a new location (i.e., to where the sea turtle is no longer within the vicinity of the intended impact location).

6 Additional Regulatory Considerations

In accordance with the Council on Environmental Quality regulations for implementing the National Environmental Policy Act (NEPA), federal agencies shall, to the fullest extent possible, integrate the requirements of NEPA with other planning and environmental review procedures required by law or by agency practice so that all such procedures run concurrently rather than consecutively. This chapter summarizes environmental compliance for the Proposed Action; consistency with other federal, state, and local plans, policies, and regulations in addition to the ones discussed in Chapter 3 (Affected Environment and Environmental Consequences); the relationship between short-term impacts and the maintenance and enhancement of long-term productivity in the affected environment; irreversible and irretrievable commitments of resources; and energy conservation.

6.1 Consistency with Other Applicable Federal, State, and Local Plans, Policies, and Regulations

Implementation of the Proposed Action in this Supplemental Environmental Impact Statement/ Overseas Environmental Impact Statement (SEIS/OEIS) would comply with applicable federal, state, and local laws, regulations, and executive orders. The United States (U.S.) Department of the Navy (Navy) has consulted with regulatory agencies, as appropriate, during the NEPA process and before implementing the Proposed Action.

Table 6.1-1 summarizes environmental compliance requirements that were considered in preparing this SEIS/OEIS (including those that may be secondary considerations in the resource evaluations). Section 3.0.2 (Regulatory Framework) provides brief excerpts of the primary federal statutes, executive orders, international standards, and guidance that form the regulatory framework for the resource evaluations. Section 1.6 (The Environmental Planning Process) provides brief excerpts of the primary federal statutes, executive orders, and guidance that form the regulatory framework for the resource evaluations in Chapter 3 (Affected Environment and Environmental Consequences). Documentation of consultation and coordination with regulatory agencies is provided in Appendix C (Agency Correspondence).

Table 6.1-1: Summary of Environmental Compliance for the Proposed Action

Statutes, Regulations, International Standards, and Guidance	Status of Compliance
Statutes and Regulations	
Abandoned Shipwreck Act (43 United States Code [U.S.C.] sections 2101-2106)	See Section 3.11 (Cultural Resources) for assessment and conclusion that the Proposed Action is consistent with the act.
Act to Prevent Pollution from Ships (33 U.S.C. sections 1901–1915)	The Navy complies with these regulations and operates in a manner that minimizes or eliminates any adverse effects to the marine environment. See Section 3.1 (Sediments and Water Quality) for the assessment.
Clean Air Act (CAA) (42 U.S.C. sections 7401 et seq.) *CAA General Conformity Rule* (40 CFR section 93[B]) State Implementation Plan (SIP)	The Proposed Action would not conflict with attainment and maintenance goals established in the State Implementation Plan. As determined previously, a CAA conformity determination will not be required because emissions attributable to the alternatives including the Proposed Action would be below *de minimis* thresholds. See the Section 3.1 (Air Quality) for discussion of training and testing activities and compliance with the CAA.
Clean Water Act (CWA) (33 U.S.C. 1251 et seq.)	No permits are required under the CWA Sections 401, 402, or 404 (b) (1) for the Proposed Action.
Coastal Zone Management Act (16 U.S.C. sections 1451-1464)	The Navy will continue compliance with *the Coastal Zone Management Act*. See Section 6.1.1 (Coastal Zone Management Act Compliance).
Endangered Species Act (ESA) (16 U.S.C. sections 1531 et seq.)	This SEIS/OEIS analyzes potential effects to species listed under the ESA and is administered by both the U.S. Fish and Wildlife Service (USFWS) and National Marine Fisheries Service (NMFS). In accordance with Section 7 of the ESA (50 CFR section 402), during the preparation of the 2015 MITT Final EIS/OEIS, the Navy prepared a biological assessment and submitted it to the USFWS. A Biological Opinion (BO) was issued by USFWS and remains valid. The Navy will continue to adhere to any BO terms and conditions listed therein. The Navy prepared a Biological Assessment that was submitted to NMFS as part of formal consultation. A BO may be issued by NMFS, and the Navy will adhere to any BO terms and conditions listed therein.

Table 6.1-1: Summary of Environmental Compliance for the Proposed Action (continued)

Statutes, Regulations, International Standards, and Guidance	Status of Compliance
Statutes and Regulations (continued)	
Historic Sites, Buildings and Antiquities Act, 1935 (54 U.S.C. 320101 et seq.) *Antiquities Act* (54 U.S.C. sections 320301–320303)	Status remains unchanged since the 2015 MITT Final EIS/OEIS. See Section 3.11 (Cultural Resources) for the assessment.
Magnuson-Stevens Fishery Conservation and Management Act (16 U.S.C. sections 1801–1882)	The Proposed Action may have potential impacts on essential fish habitat and managed species. Consultation with NMFS was conducted for affected species and their habitats (see Section 6.1.3, Magnuson-Stevens Fishery Conservation and Management Act).
Marine Mammal Protection Act (MMPA) (16 U.S.C. sections 1431 et seq.)	This SEIS/OEIS updates the analysis and was the basis for a request for a new Letter of Authorization (LOA) permit for activities beginning in 2020. The Navy applied for a LOA, which is expected to impose terms and conditions that, when implemented, would make ESA Section 9 prohibitions inapplicable to covered Navy activities.
Migratory Bird Treaty Act (16 U.S.C. sections 703–712)	The Proposed Action is not anticipated to result in significant adverse effects on migratory bird populations. The Navy did not need to confer with the U.S. Fish and Wildlife Service as a result of the Proposed Action.
Military Munitions Rule	As noted in the 2015 MITT Final EIS/OEIS, military munitions are not considered solid waste based on two conditions stated at 40 CFR section 266.202(a)(1)(i iii). These two conditions are when munitions are used for their intended purpose and when unused munitions or a component of are subject to materials recovery activities. These two conditions cover the uses of munitions included in the Proposed Action; therefore, the Resource Conservation and Recovery Act does not apply. Status remains unchanged since the 2015 MITT Final EIS/OEIS.
National Fishery Enhancement Act (33 U.S.C. section 2101 et seq.)	As noted in the 2015 MITT Final EIS/OEIS, the Proposed Action is consistent with regulations administered by NMFS and the U.S. Army Corps of Engineers concerning artificial reefs in the navigable waters of the United States. Status remains unchanged since the 2015 MITT Final EIS/OEIS. See Section 3.9 (Fishes) for the assessment.

Table 6.1-1: Summary of Environmental Compliance for the Proposed Action (continued)

Statutes, Regulations, International Standards, and Guidance	Status of Compliance
Statutes and Regulations (continued)	
National Historic Preservation Act (54 U.S.C. section 306108)	Since January 2019, the Navy has been engaged in ongoing consultations under Section 106 of the NHPA in order to replace the now expired 2009 MIRC Programmatic Agreement (PA) (U.S. Department of Defense, 2009). As the Navy continues to actively consult and develop a new PA for the MITT undertaking, the Parties have executed interim PAs which incorporate all of the terms and mitigations of the 2009 PA. The interim PAs took effect after the expiration of the 2009 MIRC PA and serve as a continuation of the DoD's compliance under Section 106 of the NHPA for MITT activities. The interim PA with the CNMI Historic Preservation Officer (HPO) expires September 10, 2020, while the interim PA with the Guam HPO expires June 30, 2020. The Proposed Action is consistent with the national policy for the preservation of historic sites, buildings, and objects of national significance. Furthermore, the Navy will comply, as applicable, with the Section 106 consultation requirements.
National Marine Sanctuaries Act (16 U.S.C. sections 1431–1445c-1)	There are no National Marine Sanctuaries within the MITT Study Area.
Rivers and Harbors Act (33 U.S.C. section 401 et seq.)	No permit is required under the Rivers and Harbors Act because no construction in navigable waterways is proposed.
The Sikes Act of 1960 (16 U.S.C. sections 670a-670o, as amended by the Sikes Act Improvement Act of 1997, Public Law No. 105-85), requires military installations with significant natural resources to prepare and implement Integrated Natural Resource Management Plans (INRMPs).	Status remains unchanged since the 2015 MITT Final EIS/OEIS. The Proposed Action and Alternatives will not result in a requirement for an update of INRMPs outside of their normal update schedule of every 5 years.
Submerged Lands Act of 1953 (43 U.S.C. sections 1301–1315)	The Proposed Action is consistent with the Submerged Lands Act regulations.
Sunken Military Craft Act (Public Law 108–375, 10 U.S.C. section 113 Note and 118 Stat. 2094–2098)	The *Sunken Military Craft Act* does not apply to actions taken by, or at the direction of, the United States.

Table 6.1-1: Summary of Environmental Compliance for the Proposed Action (continued)

Statutes, Regulations, International Standards, and Guidance	Status of Compliance
Executive Orders	
Executive Order 11990*, Protection of Wetlands*	Implementation of the Proposed Action would not affect wetlands as defined in Executive Order 11990.
Executive Order 12114, *Environmental Effects Abroad of Major Department of Defense Actions*	The Navy prepared this SEIS/OEIS in accordance with Executive Order 12114 and Navy-implementing regulations found at 32 CFR part 187, *Environmental Effects Abroad of Major Department of Defense Actions*.
Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*	As noted in the 2015 MITT Final EIS/OEIS, the Proposed Action would not result in any disproportionately high and adverse human health or environmental effects on minority or low-income populations. Status remains unchanged since the 2015 MITT Final EIS/OEIS. See Section 3.12 (Socioeconomic Resources and Environmental Justice) for the assessment.
Executive Order 12962*, Recreational Fisheries*	Status remains unchanged since the 2015 MITT Final EIS/OEIS. See Section 3.12 (Socioeconomic Resources and Environmental Justice) for the assessment.
Executive Order 13045, *Protection of Children from Environmental Health Risks and Safety Risks*	The Proposed Action would not result in disproportionate environmental health or safety risks to children. See Section 3.0.3 (Resources and Issues Not Carried Forward for More Detailed Discussion).
Executive Order 13089*, Coral Reef Protection*	Status remains unchanged since the 2015 MITT Final EIS/OEIS.
Executive Order 13112*, Invasive Species*	As noted in the 2015 MITT Final EIS/OEIS, the Navy has prepared this SEIS/OEIS in accordance with requirements for the prevention of and eradication of invasive species. Naval vessels are exempt from 33 CFR 151 Subpart D, *Ballast Water Management for Control of Non-indigenous Species in Waters of the United States*. Status remains unchanged since the 2015 MITT Final EIS/OEIS.
Executive Order 13158, *Marine Protected Areas*	Status remains unchanged since the 2015 MITT Final EIS/OEIS. See Section 6.1.2 (Marine Protected Areas) for more information.
Executive Order 13783, *Promoting Energy Independence and Economic Growth*	The Proposed Action is consistent with the policy and immediate review of all agency actions that potentially burden the safe, efficient development of domestic energy resources. This Executive Order revokes Executive Order 13653, *Preparing the United States for the Impacts of Climate Change*.

Table 6.1-1: Summary of Environmental Compliance for the Proposed Action (continued)

Statutes, Regulations, International Standards, and Guidance	Status of Compliance
Executive Orders (continued)	
Executive Order 13792, *Review of Designations Under the Antiquities Act*	On April 26, 2017, Executive Order 13792 was issued; it directed the Secretary of the Interior to review designations of national monuments made since 1996.
Executive Order 13834, *Efficient Federal Operations*	The Proposed Action is consistent with the federal government's order to prioritize actions that reduce waste, cut costs, enhance the resilience of Federal infrastructure and operations, and enable more effective accomplishment of an agency's mission. This Executive Order revokes Executive Order 13693, *Planning for Federal Sustainability in the Next Decade*.
Executive Order 13840, *Ocean Policy to Advance the Economic, Security, and Environmental Interests of the United States*	The Proposed Action is consistent with the comprehensive national policy for the *Ocean Policy to Advance the Economic, Security, and Environmental Interests of the United States* (which revoked and replaced Executive Order 13547, *Stewardship of the Ocean, Our Coasts, and the Great Lakes*).
International Standards	
International Convention for the Prevention of Pollution from Ships	As noted in the 2015 MITT Final EIS/OEIS, the Proposed Action does not include vessel operation and discharge from ships; however, the Navy vessels operating in the Study Area would comply with the discharge requirements established in this program, minimizing or eliminating potential impacts from discharges from ships. Status remains unchanged since the 2015 MITT Final EIS/OEIS.

Notes: CFR = Code of Federal Regulations, DoD = Department of Defense, EIS = Environmental Impact Statement, MBTA = Migratory Bird Treaty Act, MIRC = Mariana Islands Range Complex, MITT = Mariana Islands Training and Testing, NHPA = National Historic Preservation Act, OEIS = Overseas Environmental Impact Statement, SEIS = Supplemental Environmental Impact Statement, U.S. = United States, U.S.C. = United States Code.

6.1.1 Coastal Zone Management Act Compliance

The Coastal Zone Management Act of 1972 (16 United States Code [U.S.C.] section 1451, et seq.) encourages coastal states to be proactive in managing coastal zone uses and resources. The act established a voluntary coastal planning program and required participating states to submit a Coastal Management Plan to the National Oceanic and Atmospheric Administration for approval. Under the act, federal actions that have an effect on a coastal use or resource are required to be consistent, to the maximum extent practicable, with the enforceable policies of federally approved Coastal Management Plans.

The Coastal Zone Management Act defines the coastal zone as extending "to the outer limit of State title and ownership under the Submerged Lands Act" (i.e., 3 nautical miles [NM] or 9 NM from the shoreline, depending on the location). The coastal zone extends inland only to the extent necessary to control the shoreline, but the shoreward extent is not relevant to the Proposed Action.

A consistency determination (CD), a negative determination, or a *de minimis* exemption may be submitted for review of federal agency activities. A federal agency submits a CD when it determines that its activity may have either a direct or an indirect effect on a state coastal use or resource. In accordance with 15 Code of Federal Regulations section 930.39, the CD will include a brief statement indicating whether the proposed activity will be undertaken in a manner consistent to the maximum extent practicable with the enforceable policies of the management program. The CD must be based on evaluation of the relevant enforceable policies of the management program. In accordance with 15 Code of Federal Regulations section 930.35, "if a Federal agency determines that there will not be coastal effects, then the Federal agency shall provide the State agencies with a negative determination for a Federal agency activity: (1) Identified by a State agency on its list, as described in section 930.34(b), or through case-by-case monitoring of unlisted activities; or (2) Which is the same as or is similar to activities for which CDs have been prepared in the past; or (3) For which the Federal agency undertook a thorough consistency assessment and developed initial findings on the coastal effects of the activity." Thus, a negative determination must be submitted to a state if the agency determines no coastal effects and one or more of the triggers above is met. *De minimis* exemptions are activities proposed by the federal agency that have already been reviewed and approved by the state (after allowing for public review and comment), and those that the state has recognized as having insignificant direct or indirect (secondary or cumulative) effects on its coastal resources.

6.1.1.1 Guam Coastal Management Program

The Navy submitted a CD to the Bureau of Statistics and Plans (BSP) in December 2019 addressing proposed military training and testing activities that may affect Guam's coastal use or resource. The CD was prepared in accordance with Guam's Procedures Guide for Achieving Federal Consistency with the Guam Coastal Management Program (Bureau of Statistics and Plans May 2011). BSP's response to the Navy's CD (dated March 6, 2020) can be found in Appendix C (Agency Correspondence). The Navy is in discussions with BSP in order to resolve any differences and reach an agreement regarding the Navy's compliance with Guam's Coastal Management Program to the maximum extent practicable. The outcome of these discussions will be included in the Record of Decision.

6.1.1.2 Commonwealth of the Northern Mariana Islands Coastal Zone Management Program

The Navy submitted a CD to the Commonwealth of the Northern Mariana Islands (CNMI) Division of Coastal Resources Management (DCRM) in December 2019 addressing proposed military training and testing activities that may affect the CNMI's coastal use or resource. DCRM's response to the Navy's CD

(dated March 9, 2020) can be found in Appendix C (Agency Correspondence). The Navy is in discussions with DCRM in order to resolve any differences and reach an agreement regarding the Navy's compliance with CNMI's Coastal Management Program to the maximum extent practicable. The outcome of these discussions will be included in the Record of Decision.

6.1.2 Marine Protected Areas

The National System of Marine Protected Areas includes marine protected areas managed under six systems: (1) the National Marine Sanctuary System, (2) Marine National Monuments, (3) the National Wildlife Refuge System, (4) State and Local Marine Protected Areas, (5) the National Parks System, and (6) the National Estuarine Research Reserve System. The 2015 MITT Final EIS/OEIS discussed Marine Protected Areas that overlapped with the Study Area (U.S. Department of the Navy, 2015). There are no National Marine Sanctuary System or National Estuarine Research Reserve System areas in the Study Area. The Mariana Trench Marine National Monument (Proclamation No. 8335, 74 *Federal Register* 1557) is located within the Study Area, but was designated in 2009 with specific language that stated: "The prohibitions required by this proclamation shall not apply to activities and exercises of the Armed Forces (including those carried out by the United States Coast Guard)."

There are three national wildlife refuge areas within the Study Area: the Guam National Wildlife Refuge, the Mariana Arc of Fire National Wildlife Refuge, and the Mariana Trench National Wildlife Refuge. The Guam National Wildlife Refuge is the only one included in the National System of Marine Protected Areas. There are 12 state or local marine protected areas within the Study Area, none of which are included in the National System of Marine Protected Areas. Finally, the War in the Pacific National Historical Park is within the Study Area; however, it is not included in the National System of Marine Protected Areas. Activities proposed and regulations in these areas have not changed substantially since the 2015 MITT Final EIS/OEIS was published. Further analysis and discussion of Marine Protected Areas can be found in the 2015 MITT Final EIS/OEIS, Chapter 6 (Additional Regulatory Considerations), Table 6.1-2. Executive Order 13792, *Review of Designations Under the Antiquities Act*, authorized a review of certain designated National Monuments under the Antiquities Act by the Secretary of the Interior. No changes have been made currently to the National Monument in the Study Area.

6.1.3 Magnuson-Stevens Fishery Conservation and Management Act

The Magnuson-Stevens Fishery Conservation and Management Act of 1976 (16 U.S.C. section 1801–1891[d]), as amended by the 1996 Sustainable Fisheries Act (Public Law 104–297), and the Magnuson-Stevens Fishery Conservation and Management Reauthorization Act of 2006 (Public Law 109-479), governs marine fisheries management in U.S. waters in order to promote long-term economic and biological sustainability for fisheries up to 200 NM from shore. Its main objectives are to prevent overfishing, rebuild overfished stocks, increase long-term economic and social benefits, and ensure a safe and sustainable supply of seafood (National Oceanic and Atmospheric Administration, 2017). The Sustainable Fisheries Act of 1996 amended the law to establish procedures that identify, conserve, and enhance Essential Fish Habitat (EFH) for species regulated under a federal fisheries management plan. Consultation with the National Oceanic and Atmospheric Administration's National Marine Fisheries Service (NMFS) on all actions or proposed actions that may adversely affect EFH is required for federal agencies under section 305(b)(2) of the Magnuson-Stevens Act.

The Magnuson-Stevens Fishery Conservation and Management Act defines an adverse effect as,

> "any impact that reduces quality and/or quantity of Essential Fish Habitat. Adverse effects may include direct or indirect physical, chemical or biological alterations of the waters or substrate and the loss of, or injury to, benthic organisms, prey species and their habitat and other ecosystem components, if such modifications reduce the quality and/or quantity of Essential Fish Habitat. Adverse effects to Essential Fish Habitat may result from actions occurring within Essential Fish Habitat or outside of Essential Fish Habitat and maybe include site-specific or habitat-wide impacts, including individual, cumulative, or synergistic consequences of actions," (50 Code of Federal Regulations 600.810).

The regional Fisheries Management Councils may also designate areas called Habitat Areas of Particular Concern (HAPC). Designated HAPCs are discrete subsets of EFH that provide extremely important ecological functions or are especially vulnerable to degradation.

The Navy completed a previous EFH consultation with NMFS for the MITT Study Area in 2014. From the 2014 consultation, it was determined that certain proposed activities would affect some elements of EFH. NMFS provided conservation recommendations and the Navy agreed to certain measures to avoid, minimize, mitigate, or offset effects. EFH and HAPC designations in the Study Area have not changed and the previous 2014 consultation is still valid for the proposed training and testing activities that have not changed. The Navy conducted a supplemental EFH consultation with the NMFS Pacific Island Regional Office considering activities that are new or that have changed since the 2014 EFH consultation and that have the potential to adversely affect EFH and managed species for this SEIS/OEIS.

6.2 Relationship Between Short-Term Use of the Environment and Maintenance and Enhancement of Long-Term Productivity

In accordance with the Council on Environmental Quality regulations (Part 1502), this SEIS/OEIS analyzes the relationship between the short-term impacts on the environment and the effects those impacts may have on the maintenance and enhancement of the long-term productivity of the affected environment. This analysis has not changed since the analysis conducted in the 2015 MITT Final EIS/OEIS. See Section 6.2 (Relationship Between Short-Term Use of The Environment and Maintenance and Enhancement of Long-Term Productivity) of the 2015 MITT Final EIS/OEIS for more information (U.S. Department of the Navy, 2015).

6.3 Irreversible or Irretrievable Commitment of Resources

NEPA requires that environmental analysis include identification of "any irreversible and irretrievable commitments of resources which would be involved in the Proposed Action should it be implemented" (42 U.S.C. section 4332). This analysis has not changed since it was conducted in the 2015 MITT Final EIS/OEIS. See Section 6.3 (Irreversible or Irretrievable Commitment of Resources) of the 2015 MITT Final EIS/OEIS for more information (U.S. Department of the Navy, 2015).

6.4 Energy Requirements and Conservation Potential of Alternatives

Under the operational strategy report in 2011, the Department of Defense (DoD) published an implementation plan to integrate operational energy considerations and transformation into existing programs, processes, and institutions (U.S. Department of Defense, 2012). In fiscal year (FY) 2015, the Navy reduced its petroleum consumption by 25.1 percent compared to the FY 2005 baseline (U.S. Department of Defense, 2016a). In 2016, the DoD published a new *Operational Energy Strategy*

(U.S. Department of Defense, 2016b) to update the 2011 strategy and transform the way energy is consumed in military operations. The 2011 strategy set the overall direction for operational energy security (U.S. Department of Defense, 2011). The 2016 strategy shifts focus towards three objectives: (1) increasing future warfighting capability by including energy throughout future force development, (2) identifying and reducing logistic and operational risks from operational energy vulnerabilities, and (3) enhancing the force's mission effectiveness through updated equipment and improvements in training, exercises, and operations (U.S. Department of Defense, 2016b). These documents guide the DoD in how to better use energy resources and transform the way we power current and future forces.

This strategy is consistent with energy conservation practices and states that the Navy values energy as a strategic resource, understands how energy security is fundamental to executing our mission afloat and ashore, and is resilient to any potential energy future. The DoD *Fiscal Year 2018 Operational Energy Annual Report* (2019) satisfies the requirements in section 2925(b) of title 10 U.S.C. for FY 2018 and includes information on operational energy demands, progress in implementing the *Operational Energy Strategy* (2016b), alternative fuels investments, and contingency operations support. The DoD consumed approximately 85 million barrels of fuel to power ships, aircraft, combat vehicles, and contingency bases in FY 2018 (Department of Defense, 2019). The Navy consumes approximately 26 percent of the total DoD share (Department of Defense, 2019).

Training and testing activities within the Study Area would increase energy demand over the No Action Alternative. The energy demand would arise from fuel (e.g., gasoline, diesel) consumption, mainly from aircraft and vessels participating in training and testing. Details of fuel consumption by training and testing activities on an annual basis are outlined in the air quality emissions calculation spreadsheets available on the project website. Calculations from the air quality analysis in this SEIS/OEIS found that aircraft fuel consumption is estimated to decrease by approximately 5 percent per year under both Alternative 1 and Alternative 2, when compared to current annual rates of aircraft fuel consumption. Vessel fuel consumption is estimated to increase by approximately 8 percent per year under both Alternative 1 and Alternative 2, when compared to current annual rates of vessel fuel consumption. Conservative assumptions were made in developing the estimates, and therefore the actual amount of fuel consumed during training and testing events may be less than estimated. The alternatives could result in a net cumulative reduction in the global energy (fuel) supply.

Energy requirements would be subject to any established energy conservation practices. The use of energy sources has been minimized wherever possible without compromising safety, training, or testing activities. No additional conservation measures related to direct energy consumption by the proposed activities are identified. The Navy's energy vision given in the *2016 Operational Energy Strategy* report (U.S. Department of Defense, 2016b) is consistent with energy conservation practices and states that the Navy values energy as a strategic resource, understands how energy security is fundamental to executing our mission afloat and ashore and is resilient to any potential energy future.

The Navy is committed to improving energy security and environmental stewardship by reducing its reliance on fossil fuels. The Navy is actively developing and participating in energy, environmental, and climate change initiatives that will help conserve the world's resources for future generations. The Navy Climate Change Roadmap identified actions the Environmental Readiness Division took to implement Executive Order 13653, *Preparing the United States for the Impacts of Climate Change* (which has since been revoked and replaced with Executive Order 13783, *Promoting Energy Independence and Economic Growth*).

The Navy is committed to improving energy security and environmental stewardship by reducing its reliance on fossil fuels (U.S. Department of the Navy, n.d.). The Navy is actively developing and participating in energy, environmental, and climate change initiatives that will increase the use of alternative energy and help conserve the world's resources for future generations. Examples of Navy-wide greenhouse gas reduction projects include energy-efficient construction, thermal and photovoltaic solar systems, geothermal power plants, and the generation of electricity with wind energy. The Navy continues to promote and install new renewable energy projects.

Two Navy programs—the Incentivized Energy Conservation Program and the Naval Sea Systems Command's Fleet Readiness, Research, and Development Program—are helping the Fleet conserve fuel via improved operating procedures and long-term initiatives. The Incentivized Energy Conservation Program encourages the operation of ships in the most efficient manner while conducting their mission and supporting the Secretary of the Navy's efforts to reduce total energy consumption on naval ships. The Naval Sea Systems Command's Fleet Readiness, Research, and Development Program includes the High-Efficiency Heating, Ventilating, and Air Conditioning; and the Hybrid Electric Drive for DDG-51 class ships, which are improvements to existing shipboard technologies that will both help with Fleet readiness and decrease the ships' energy consumption and greenhouse gas emissions. These initiatives are expected to greatly reduce the consumption of fossil fuels.

8 Public Involvement and Distribution

This chapter includes a summary of the public involvement and stakeholder outreach activities conducted by the United States (U.S.) Navy (Navy) during the scoping period and the public review and comment period for the Draft Supplemental Environmental Impact Statement (SEIS)/Overseas Environmental Impact Statement (OEIS) for Mariana Islands Training and Testing (MITT). The scoping period ran from July 28, 2017, through September 15, 2017. The Draft SEIS/OEIS was released for public review and comment February 1, 2019, through April 17, 2019.

The purpose of public involvement during the public scoping period was to (1) notify and inform stakeholders and the public about the Proposed Action; and (2) provide opportunities for the public to comment on the scope of the analysis, including environmental issues and potential viable alternatives. The purpose of public involvement and outreach during the public review and comment period of the Draft SEIS/OEIS was to (1) notify and inform stakeholders and the public about the Proposed Action and the release of the Draft SEIS/OEIS, and (2) provide the opportunity for the public and stakeholders to comment on the Draft SEIS/OEIS.

Public Outreach and involvement efforts were conducted in accordance with the National Environmental Policy Act and Navy guidance.

8.1 Project Website

A public website was established to provide the public with project, public meeting, and commenting information, and to accept comments electronically. The project website address is www.mitt-eis.com and has been active since 2014.

The website address was included in the *Federal Register* (FR) notices: Notice of Intent to Prepare an SEIS/OEIS, Notice of Availability of the Draft SEIS/OEIS, Notice of Public Meetings, Notice of Rescheduled Meetings, and Notice of Extension of Public Comment Period. It was also included in newspaper advertisements, agency letters, press releases, and postcard mailers.

Public notifications, fact sheet booklets, maps, technical reports, informational videos, and other public involvement information are available on the project website and will be available throughout the course of the project. The website is periodically updated with project announcements, which are emailed to website subscribers.

8.2 Scoping Period

The public scoping period began with issuance of the Notice of Intent in the *Federal Register* July 28, 2017, originally announcing the scoping period to end September 11, 2017, but was delayed slightly by the publication authority. However, the *Federal Register* notice was published on August 1, 2017 (82 FR 35767), with a September 15, 2017, scoping period end date. Comments on the scope of the analysis were provided by mail and through the project website. The *Federal Register* Notice of Intent for Scoping is shown in Figure 8.2-1.

Department of the Navy

Meeting of the Board of Visitors of Marine Corps University

AGENCY: Department of the Navy, DOD.
ACTION: Notice of open meeting.

SUMMARY: The Board of Visitors of the Marine Corps University (BOV MCU) will meet to review, develop and provide recommendations on all aspects of the academic and administrative policies of the University; examine all aspects of professional military education operations; and provide such oversight and advice, as is necessary, to facilitate high educational standards and cost effective operations. The Board will be focusing primarily on the internal procedures of Marine Corps University. All sessions of the meeting will be open to the public.

DATES: The meeting will be held on Thursday, September 14, 2017, from 9:00 a.m. to 4:30 p.m. and Friday, September 15, 2017, from 8:00 a.m. to 2:30 p.m. Eastern Time Zone.

ADDRESSES: The meeting will be held at Marine Corps University in Quantico, Virginia. The address is: 2076 South St., Quantico, VA.

FOR FURTHER INFORMATION CONTACT: Dr. Kim Florich, Director of Faculty Development and Outreach, Marine Corps University Board of Visitors, 2076 South Street, Quantico, Virginia 22134, telephone number 703–432–4682.

Dated: July 24, 2017.

A.M. Nichols,

Lieutenant Commander, Judge Advocate General's Corps, U.S. Navy, Federal Register Liaison Officer.

DEPARTMENT OF DEFENSE

Department of the Navy

Notice of Intent To Prepare a Supplemental Environmental Impact Statement/Overseas Environmental Impact Statement for Mariana Islands Training and Testing

AGENCY: Department of the Navy, DOD.
ACTION: Notice.

SUMMARY: Pursuant to the National Environmental Policy Act (NEPA) of 1969 and regulations implemented by the Council on Environmental Quality, the Department of the Navy (DoN) announces its intent to prepare a supplement to the 2015 Final Mariana Islands Training and Testing (MITT) Environmental Impact Statement/ Overseas Environmental Impact Statement (EIS/OEIS).

DATES: Public scoping meetings will not be held, but public comments will be accepted during the scoping period from August 1, 2017 to September 15, 2017.

ADDRESSES: The DoN invites scoping comments on the MITT Supplemental EIS/OEIS from all interested parties. Substantive comments may be provided by mail to the address below and through the project Web site at *http://mitt-eis.com/*. Comments must be postmarked or received by September 15, 2017, for consideration during the development of the Draft Supplemental EIS/OEIS.

FOR FURTHER INFORMATION CONTACT: Naval Facilities Engineering Command Pacific, Attention: MITT Supplemental EIS/OEIS Project Manager, 258 Makalapa Drive, Suite 100, Pearl Harbor, HI 96860–3134.

SUPPLEMENTARY INFORMATION: The Navy will assess the potential environmental impacts associated with ongoing and proposed military readiness activities conducted within the MITT EIS/OEIS Study Area (hereafter known as the "Study Area"). The Supplement to the 2015 Final EIS/OEIS is being prepared to support ongoing and future activities conducted at sea and on Farallon de Medinilla (FDM) within the Study Area beyond 2020. Military readiness activities include training and research, development, testing, and evaluation (hereafter known as "testing"). The Supplemental EIS/OEIS will include an analysis of training and testing activities using new information available after the release of the 2015 Final MITT EIS/OEIS. New information includes an updated acoustic effects model, updated marine mammal density data, and other best available science. Proposed activities are generally consistent with those analyzed in the 2015 Final MITT EIS/OEIS and are representative of training and testing activities the DoN has been conducting in the Study Area for decades.

The Study Area remains unchanged since the 2015 Final MITT EIS/OEIS. The Study Area includes the existing Mariana Islands Range Complex (MIRC); areas on the high seas to the north and west of the MIRC; a transit corridor between the MIRC and the Hawaii Range Complex, starting at the International Date Line; and Apra Harbor and select DoN pierside and harbor locations. The Study Area includes only the in-water components of the range complex and FDM; land components associated with the range complex are not included in the Study Area.

As part of this process the DoN will seek the issuance of regulatory permits and authorizations under the Marine Mammal Protection Act and Endangered Species Act to support training and testing requirements within the Study Area, beyond 2020, thereby ensuring critical Department of Defense requirements are met.

Pursuant to 40 CFR 1501.6, the DoN will invite the National Marine Fisheries Service to be a cooperating agency in preparation of the Supplemental EIS/OEIS.

Figure 8.2-1: Notice of Intent for Scoping

The DoN's lead action proponent is Commander, U.S. Pacific Fleet. Additional action proponents include Naval Sea Systems Command, Naval Air Systems Command, and the Office of Naval Research.

The DoN's Proposed Action is to conduct military training and testing activities within the Study Area. Activities include the use of active sonar and explosives while employing appropriate marine species protective mitigation measures. The Proposed Action does not alter the DoN's original purpose and need as presented in the 2015 MITT Final EIS/OEIS.

The purpose of the Proposed Action is to maintain a ready force, which is needed to ensure the military can accomplish its mission to maintain, train, and equip combat-ready naval forces capable of winning wars, deterring aggression, and maintaining freedom of the seas, consistent with Congressional direction in section 5062 of Title 10 of the U.S. Code. A Supplemental EIS/OEIS is considered the appropriate document, as there is recent scientific information including revised acoustic criteria to consider, in furtherance of NEPA, relevant to the environmental effects of the DoN's Proposed Action, and the analysis will support Marine Mammal Protection Act authorization requests.

Proposed training and testing activities are generally consistent to those analyzed in the 2015 MITT Final EIS/OEIS. The Supplemental EIS/OEIS will propose changes to the tempo and types of training and testing activities, accounting for the introduction of new technologies, the evolving nature of international events, advances in war fighting doctrine and procedures, and changes in the organization of vessels, aircraft, weapon systems, and military personnel. The MITT Supplemental EIS/OEIS will reflect the compilation of training and testing activities required to fulfill the DoN's military readiness requirements beyond 2020, and therefore includes the analysis of newly proposed activities and changes to previously analyzed activities.

In the Supplemental EIS/OEIS, the DoN will evaluate the potential environmental impacts of a No Action Alternative and action alternatives. Resources to be evaluated include, but are not limited to, marine mammals, sea turtles, essential fish habitat, and threatened and endangered species.

The scoping process is used to identify public concerns and local issues to be considered during the development of the Draft Supplemental EIS/OEIS. Federal agencies, local agencies, the public, and interested persons are encouraged to provide substantive comments to the DoN on environmental resources and issue areas of concern the commenter believes the DoN should consider.

Comments must be postmarked or received online by September 15, 2017, for consideration during the development of the Draft Supplemental EIS/OEIS. Comments can be mailed to: Naval Facilities Engineering Command Pacific, Attention: MITT Supplemental EIS/OEIS Project Manager, 258 Makalapa Drive, Suite 100, Pearl Harbor, HI, 96869–3134. Comments can be submitted online via the project Web site at *http://mitt-eis.com/*.

Dated: July 20, 2017.

A.M. Nichols,

Lieutenant Commander, Judge Advocate General's Corps, U.S. Navy, Federal Register Liaison Officer.

BILLING CODE 3810–FF–P

DEPARTMENT OF EDUCATION

Final Waiver and Extension of the Project Period for the Native American Career and Technical Education Program

[Catalog of Federal Domestic Assistance (CFDA) Number: 84.101A]

AGENCY: Office of Career, Technical, and Adult Education, Department of Education.

ACTION: Final waiver and extension of the project period.

SUMMARY: For the 24-month projects originally funded in fiscal year (FY) 2013 and extended for an additional 24-months in FY 2015 under the Native American Career and Technical Education Program (NACTEP), the Secretary: Waives the requirements in Education Department regulations that generally prohibit project extensions involving the obligation of additional Federal funds; and extends the project period for the current 30 NACTEP grantees for an additional 12 months under the existing program authority. This waiver and extension will allow the 30 current NACTEP grantees to seek FY 2017 continuation awards for the project period through FY 2018.

DATES: As of August 1, 2017, the waiver and extension of the project period are finalized.

FOR FURTHER INFORMATION CONTACT: Gwen Washington by telephone at (202) 245–7790 or by email at *gwen.washington@ed.gov*. You may also contact Linda Mayo by telephone at (202) 245–7792 or by email at *linda.mayo@ed.gov*. If you use a telecommunications device for the deaf (TDD) or a text telephone (TTY), call the Federal Relay Service, toll free, at 1–800–877–8339.

SUPPLEMENTARY INFORMATION: On April 26, 2017, we published a notice in the **Federal Register** (82 FR 19240) proposing to waive the requirements of 34 CFR 75.261(a) and (c)(2) that generally prohibit project period extensions involving the obligation of additional Federal funds. In that notice, the Secretary also proposed to extend the NACTEP project period for up to an additional 12 months. The proposed waiver and extension of project period would enable the Secretary to provide continuation awards to the current NACTEP grantees through FY 2018 under the existing program authority.

That notice contained background information and our reasons for proposing the waiver and extension of the project period. This notice makes the waiver and extension of the project period final. Any activities carried out during the period of a NACTEP continuation award must be consistent with, or a logical extension of, the scope, goals, and objectives of the grantee's application as approved in the FY 2013 NACTEP competition. The requirements applicable to continuation awards for this competition set forth in the 2013 notice inviting applications and the requirements in 34 CFR 75.253 will apply to any continuation awards sought by the current NACTEP grantees.

We will make decisions regarding the continuation awards based on grantee program narratives, budgets and budget narratives, program performance reports, and the requirements in 34 CFR 75.253. We will not announce a new competition or make new awards in FY 2017.

The final waiver and project period extension will not exempt the current NACTEP grantees from the appropriation account closing provisions of 31 U.S.C. 1552(a), nor will it extend the availability of funds previously awarded to current NACTEP grantees. As a result of 31 U.S.C. 1552(a), appropriations available for a limited period may be used for payment of valid obligations for only five years after the expiration of their period of availability for Federal obligation. After that time, the unexpended balance of those funds is canceled and returned to the U.S. Department of the Treasury and is unavailable for restoration for any purpose (31 U.S.C. 1552(b)).

Public Comment: In response to our invitation in the proposed waiver and extension, we received 85 comments.

DEPARTMENT OF THE NAVY
COMMANDER
UNITED STATES PACIFIC FLEET
250 MAKALAPA DRIVE
PEARL HARBOR, HAWAII 96860-3131

IN REPLY REFER TO:
5090
Ser N465/0822
July 19, 2017

The Honorable Madeleine Z. Bordallo
U.S. Congress
120 Father Dueñas Avenue, Suite 107
Hagåtña, GU 96910

Dear Congresswoman Bordallo:

SUBJECT: NOTICE OF INTENT TO PREPARE A SUPPLEMENTAL ENVIRONMENTAL IMPACT STATEMENT/OVERSEAS ENVIRONMENTAL IMPACT STATEMENT FOR MARIANA ISLANDS TRAINING AND TESTING

This letter is to inform you that the Department of the Navy (Navy) is preparing a supplement to the 2015 Final Mariana Islands Training and Testing (MITT) Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS) to assess the potential environmental impacts associated with ongoing military readiness activities conducted within the MITT EIS/OEIS Study Area (hereafter referred to as the "Study Area"). Military readiness activities include training and research, development, testing, and evaluation (hereafter referred to as "training and testing"). The Navy is requesting your comments on the scope of the analysis, including potential environmental issues or viable alternatives to be considered during the development of the Draft Supplemental EIS/OEIS.

The Navy previously completed an EIS/OEIS in May 2015 for training and testing activities occurring within the Study Area. The supplement to the 2015 Final EIS/OEIS is being prepared to support ongoing and future activities conducted at-sea and on Farallon de Medinilla (FDM) within the Study Area beyond 2020. Proposed activities are generally consistent with those analyzed in the 2015 Final EIS/OEIS and are representative of activities the military has conducted in the Study Area for decades.

The supplement to the 2015 Final EIS/OEIS will include an analysis of training and testing activities using new information available after the release of the 2015 Final EIS/OEIS. New information includes an updated acoustic effects model, updated marine mammal density data, and evolving and emergent best available science. As part of this process, the Navy will seek the issuance of federal regulatory permits and authorizations under the Marine Mammal Protection Act and the Endangered Species Act.

The Study Area remains unchanged since the 2015 Final EIS/OEIS (Enclosure 1). The Study Area includes the existing Mariana Islands Range Complex (MIRC); areas on the high seas to the north and west of the MIRC; a transit corridor between the MIRC and the Hawaii

Figure 8.2-2: Stakeholder Scoping Notification Letter

5090
Ser N465/0822
July 19, 2017

Range Complex, starting at the International Date Line; and Apra Harbor and select Navy pierside and harbor locations. The supplement to the 2015 Final EIS/OEIS will only analyze those training and testing activities conducted at sea and on FDM within the Study Area. Other activities and land components associated with the MIRC will not be included in the supplement.

The Proposed Action is to conduct at-sea training and testing activities within the Study Area. Activities include the use of active sonar and explosives while employing marine species protective mitigation measures. The purpose of the Proposed Action is to maintain a ready force, which is needed to ensure the military can accomplish its mission to maintain, train, and equip combat-ready forces, consistent with Congressional direction in Section 5062 of Title 10 of the U.S. Code.

To achieve and maintain military readiness, the Navy proposes to:

- Conduct at-sea training and testing activities at levels required to support military readiness requirements beyond 2020; and
- Accommodate evolving mission requirements, including those resulting from the development, testing, and introduction of new vessels, aircraft, and weapons systems into the fleet.

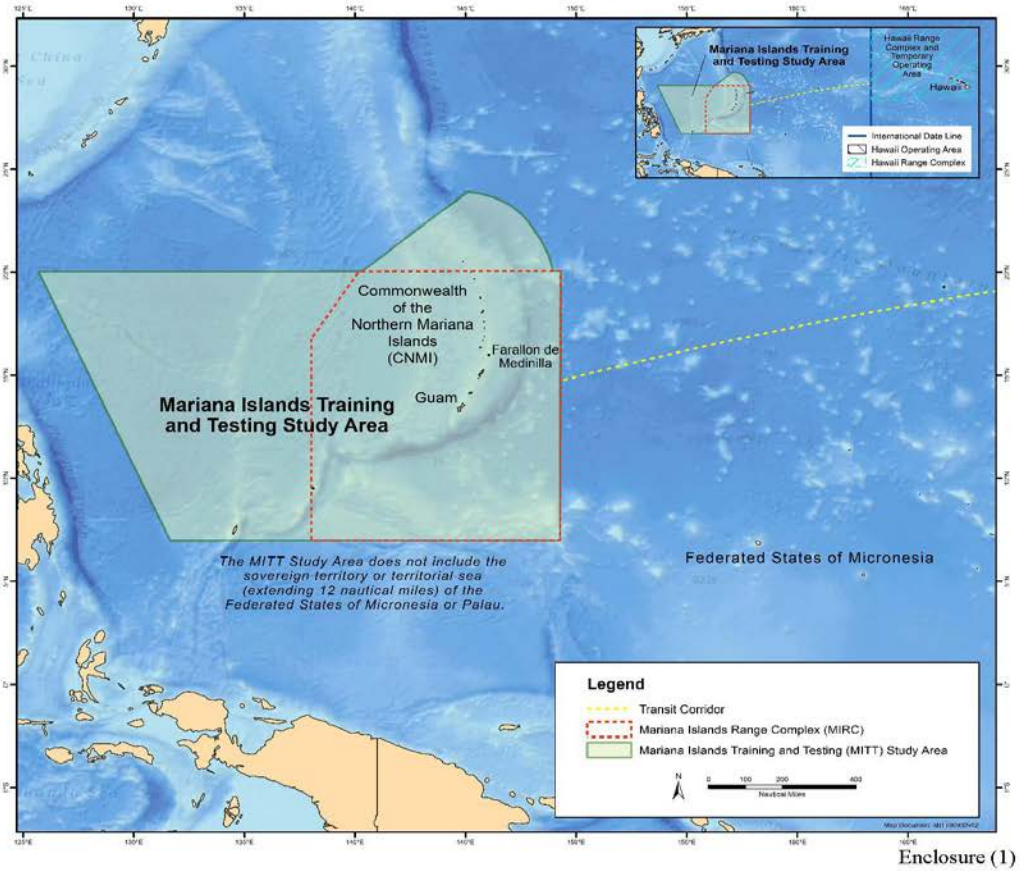
Public comments will be accepted during the 45-day scoping period beginning July 28, 2017 through September 11, 2017. Comments must be postmarked or received online by **September 11, 2017,** Chamorro Standard Time (ChST), for consideration in the Draft Supplemental EIS/OEIS. Comments may be submitted online at **www.MITT-EIS.com**, or by mail to:

Naval Facilities Engineering Command Pacific
Attention: MITT Supplemental EIS/OEIS Project Manager
258 Makalapa Drive, Suite 100
Pearl Harbor, HI 96860-3134

If you would like additional information or to receive a project briefing, please contact Mr. John Van Name at 808-471-1714 or john.vanname@navy.mil.

Please help the Navy inform the community about the Draft Supplemental EIS/OEIS for at-sea training and testing by sharing this information with your staff and interested individuals.

Sincerely,



FOR L. M. FOSTER
By direction

FOR IMMEDIATE RELEASE
Press Release 17-063

U.S. Navy Seeks Public Input on Training and Testing Supplemental Environmental Impact Analysis

ASAN, Guam (July 28, 2017) –The U.S. Navy is preparing a Supplemental Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS) to assess the potential environmental impacts associated with ongoing at-sea military readiness activities conducted within the Mariana Islands Training and Testing (MITT) EIS/OEIS Study Area (hereafter referred to as the "Study Area").

Military readiness activities include training and research, development, testing, and evaluation (hereafter referred to as "training and testing"). The Navy is requesting public comments on the scope of the analysis, including potential environmental issues and viable alternatives to be considered during the development of the Draft Supplemental EIS/OEIS.

The Navy previously completed an EIS/OEIS in May 2015 for at-sea training and testing activities occurring within the Study Area. The supplement to the 2015 Final EIS/OEIS is being prepared to support ongoing and future activities conducted at sea and on Farallon de Medinilla (FDM) within the Study Area beyond 2020. Proposed training and testing activities are generally consistent with those analyzed in the 2015 Final EIS/OEIS and represent activities the military has conducted in the Study Area for decades.

The Supplemental EIS/OEIS will include an analysis of training and testing activities using new information available after the release of the 2015 Final EIS/OEIS. New information includes an updated acoustic effects model, updated marine mammal density data, and evolving and emergent best available science. As part of this process, the Navy will seek the issuance of federal regulatory permits and authorizations under the Marine Mammal Protection Act and the Endangered Species Act.

Proposed Action:
The Proposed Action is to conduct at-sea training and testing activities within the Study Area. At-sea training and testing activities include the use of active sonar and explosives while employing marine species protective mitigation measures.

-more-

Figure 8.2-5: Press Release for Scoping

The purpose of the Proposed Action is to maintain a ready force, which is needed to ensure the military can accomplish its mission to maintain, train, and equip combat-ready forces, consistent with Congressional direction in Section 5062 of Title 10 of the U.S. Code.

To achieve and maintain military readiness, the Navy proposes to:

- Conduct at-sea training and testing activities at levels required to support military readiness requirements beyond 2020; and
- Accommodate evolving mission requirements, including those resulting from the development, testing, and introduction of new vessels, aircraft, and weapons systems into the fleet.

The Study Area remains unchanged since the 2015 Final EIS/OEIS and includes the existing Mariana Islands Range Complex (MIRC); areas on the high seas to the north and west of the MIRC; a transit corridor between the MIRC and the Hawaii Range Complex, starting at the International Date Line; and Apra Harbor and select Navy pierside and harbor locations. In the supplement to the 2015 Final EIS/OEIS, the Navy will only analyze those training and testing activities conducted at sea and on FDM within the Study Area. Other activities and land components associated with the MIRC are not included in the supplement.

Scoping Comment Period for the Supplemental EIS/OEIS:
The 45-day scoping comment period is July 28-Sept. 11. Comments must be postmarked or received online by **Sept. 11, 2017**, Chamorro Standard Time (ChST), for consideration in the development of the Draft Supplemental EIS/OEIS. All comments submitted during the 45-day public comment period will become part of the public record. Comments may be submitted online at: **www.MITT-EIS.com**, or by mail to:

Naval Facilities Engineering Command Pacific

Figure 8.2-5: Press Release for Scoping (continued)

8.2.2 Summary of Public Scoping Comments

Scoping comments were submitted in two ways:

- Written letters (received any time during the public comment period)
- Comments submitted directly on the project website (received any time during the public comment period)

The Navy received a total of 36 written and electronic comments from federal agencies, state agencies, nongovernmental organizations, individuals, and community groups. Thirty website comments were submitted using the electronic comment form on the project website. Six written comments were mailed. A sampling of some of the specific concerns follows.

8.2.2.1 Description of the Proposed Action and Alternatives

Comments stated that the description of the action and proposed activities is vague in the SEIS/OEIS and that it should include an explanation of the differences between the 2015 Record of Decision and the action proposed in this SEIS/OEIS. Comments included a request that a range of alternatives be considered, including time or seasonal restrictions, restrictions in biologically sensitive areas, reduced training and testing tempo, and mitigated alternatives.

8.2.2.2 National Environmental Policy Act and Public Involvement

Comments stated that there is a lack of detail regarding the scope of the Proposed Action presented to the public. It was suggested the website include the updated acoustic effects model, updated marine mammal density data, and the 2015 MITT Final EIS/OEIS. The scoping period was thought to be too short and should be extended.

8.2.2.3 Location of Activities

Comments stated that military training should not be conducted in the CNMI.

8.2.2.4 Indirect and Cumulative Impacts

Comments included requests that all Department of Defense actions in the Mariana Islands be analyzed for cumulative effects. Comments also included requests to analyze indirect and cumulative impacts as they relate to seagrass, coral reefs, invertebrates, sea turtles, fish populations, and loss of habitat, as well as the ocean as an ecosystem. Comments also included recommendations that recreational fishing, commercial fishing, and transport be analyzed from a cumulative perspective. Comments in this category expressed concern about the overall impact of military activity in Guam and the overall MITT Study Area.

8.2.2.5 Sediments and Water Quality Impacts

Comments stated that there was a lack of studies regarding impacts on the waters around Farallon de Medinilla (FDM) and documentation of the loss of land at FDM in regard to erosion. Requests were made to provide a detailed analysis of the residence times of constituents, effects of deposition, bioaccumulation of metals and other pollutants, and concentration of explosives and unexploded ordnance in the ocean environment, due to concerns about military expended materials becoming marine debris.

8.2.2.6 Socioeconomic Resources

Comments stated that military training activities are disturbing economically important fishing areas, restricting access to prime fishing grounds, and resulting in contamination in the local food supply. Issues raised in regard to socioeconomic impacts included increased transit times around restricted areas and associated loss of revenue due to transit times and restricted access to fishing areas.

8.2.2.7 Terrestrial Species and Habitats/Marine Birds

Comments included requests for the reevaluation of booby populations and to address impacts on the great frigate bird, red-tailed tropicbird, white-tailed tropicbird, brown noddy, and black noddy on FDM.

8.2.2.8 Marine Resources

Comments stated concerns regarding direct and cumulative impacts from military expended material and debris on the marine environment. Comments included suggestions to analyze sonar, chemical pollutants, and marine debris associated with training activities on all marine species. Monitoring results should be made available and integrated into the analysis. Impacts should also be analyzed in regard to invasive species and marine biosecurity threats. Impacts on coastal resources should be substantively analyzed under a range of alternatives and specific mitigation. Impacts on Habitat Area of Concern for Coral Reef Ecosystem Management Unit Species and Bottomfish Management Units Species should also be analyzed. Commenters stated that there were a lack of studies documenting the amount of ordnance debris and unexploded ordnance in the water and impacts on and around FDM, including coral reefs.

8.2.2.9 Marine Mammal Impacts/Sea Turtles

Comments in this category included concerns regarding the health and safety effects on marine mammals from training activities. Commenters expressed concern regarding impacts on marine mammals from sonar and explosives as well as impacts on humpback whale calving grounds.

8.2.2.10 Fish/Marine Habitat

Comments stated that training activities are disturbing pelagic and economically important fishing areas and causing fish to leave the Study Area. There were also concerns regarding acoustic disturbance to fish.

8.2.2.11 Cultural Resources

Comments stated the U.S. Navy has not consulted with indigenous people for conducting military training in the Mariana Islands. Direct and cumulative impacts need to be identified due to the loss of access to FDM for cultural use.

8.2.2.12 Public Health and Safety

Comments included concerns regarding overall impacts and risks to public health and safety in regard to unexploded ordnance, water contamination, and proper safety measures.

8.2.2.13 Mitigation Measures

Comments included requests to provide details associated with the actions the Navy will take to avoid harming protected marine mammals and coral reefs as well as the effectiveness of past mitigation measures. Comments stated that the public needs a better understanding of how mitigation measures avoid impacts on marine mammals and the effectiveness of those measures.

8.2.2.14 Other

This category includes comments that were considered to be outside the scope of this analysis or not considered applicable to the analysis. For example, there were comments related to the potential dangers posed by North Korea, direct compensation for loss of fishing grounds or the development of fishery infrastructure, the militarization of the Mariana Islands, lack of specific surveys, and third-party assessments of impacts and surveys.

8.3 Draft Supplemental Environmental Impact Statement/Overseas Environmental Impact Statement Public Review and Comment Period

The Draft SEIS/OEIS public review and comment period began with issuance of the Notice of Public Meetings (84 FR 677) January 31, 2019, and the Notice of Availability (84 FR 1119) February 1, 2019, in the *Federal Register*. A Notice of Rescheduled Public Meetings and Extension of Public Comment Period was published in the *Federal Register* (84 FR 8515) March 8, 2019. A Notice of Extension of Public Comment Period was published in the *Federal Register* (84 FR 12239) April 1, 2019. The *Federal Register* notices for the Draft SEIS/OEIS are shown in Figure 8.3-1, Figure 8.3-2, Figure 8.3-3, and Figure 8.3-4.

The *Federal Register* notices included notification of the availability of the Draft SEIS/OEIS and where it can be accessed; an overview of the Proposed Action and its purpose and need; public commenting information; and locations, dates, and times of the public meetings. The purpose of the public meetings was to inform the public about the Proposed Action and to solicit public comments on the environmental issues addressed and analyzed in the Draft SEIS/OEIS. Comments were accepted by mail, through the SEIS/OEIS website at www.mitt-eis.com, and at the public meetings.

Federal Register / Vol. 84, No. 21 / Thursday, January 31, 2019 / Notices 677

Authority: 35 U.S.C. 207, 37 CFR part 404.

Dated: January 28, 2019.

BILLING CODE 3810–FF–P

DEPARTMENT OF DEFENSE

Department of the Navy

Notice of Public Meetings for the Draft Supplemental Environmental Impact Statement/Overseas Environmental Impact Statement for Mariana Islands Training and Testing

AGENCY: Department of the Navy, DoD.

ACTION: Notice.

SUMMARY: Pursuant to section 102(2)(c) of the National Environmental Policy Act (NEPA) of 1969, as implemented by the Council on Environmental Quality, and Presidential Executive Order (E.O.) 12114, the Department of the Navy (DoN) has prepared and filed with the U.S. Environmental Protection Agency a Draft Supplemental Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS). In the Draft Supplemental EIS/OEIS, the DoN reassesses the potential environmental impacts associated with conducting ongoing and future military readiness activities, which includes training activities and research, development, testing, and evaluation activities (referred to as "testing activities") conducted at sea and on Farallon de Medinilla (FDM) within the Mariana Islands Training and Testing (MITT) Study Area (hereafter referred to as the Study Area) beyond 2020. In the Draft Supplemental EIS/OEIS, the DoN evaluates new, relevant information, such as more recent marine mammal density data and new scientific information, and updates the environmental analyses as appropriate. The DoN prepared the Draft Supplemental EIS/OEIS to support the issuance of federal regulatory permits and authorizations under the Marine Mammal Protection Act and the Endangered Species Act. The National Marine Fisheries Service (NMFS) is a cooperating agency for this Supplemental EIS/OEIS.

DATES: This notice announces the public comment period and the dates and locations of the public meetings, includes information about how the public can review and comment on the document, and provides supplementary information about the environmental planning effort. All comments must be postmarked or received online by March 18, 2019, Chamorro Standard Time, for consideration in the Final Supplemental EIS/OEIS. Federal and local agencies and officials, and interested organizations and individuals, are encouraged to provide substantive comments on the Draft Supplemental EIS/OEIS during the public review period or in person at one of the scheduled open house public meetings.

ADDRESSES: Public meetings will be held in an open-house format, with DoN representatives available to provide information and answer questions related to the Draft Supplemental EIS/OEIS. Open house public meetings will be held on Guam and Saipan. The public may arrive at any time during the open house, as there will not be a presentation or formal oral comment session. Open house public meetings will be held on the following dates and at the following locations:

1. 5:00 to 8:00 p.m. February 26, 2019, at University of Guam, Jesus & Eugenia Leon Guerrero School of Business and Public Administration Building, Anthony Leon Guerrero Multi-Purpose Room 129 and Henry Sy Atrium, Mangilao, Guam 96923.

2. 5:00 to 8:00 p.m. February 27, 2019, at Kanoa Resort Saipan, Seaside Hall, Beach Road in Susupe, Saipan, MP 96950.

Attendees will be able to submit written comments during the open house public meetings. A stenographer will be available for attendees wishing to provide oral comments, one-on-one. Equal weight will be given to oral and written comments. Comments may also be mailed to Naval Facilities Engineering Command Pacific, Attention: MITT Supplemental EIS/OEIS Project Manager, 258 Makalapa Drive, Suite 100, Pearl Harbor, HI 96860–3134, or electronically via the project website at *www.MITT-EIS.com*. All comments, written or oral, submitted during the public comment period will become part of the public record and substantive comments will be addressed in the Final Supplemental EIS/OEIS.

FOR FURTHER INFORMATION CONTACT: Naval Facilities Engineering Command Pacific, Attention: MITT Supplemental EIS/OEIS Project Manager, 258 Makalapa Drive, Suite 100, Pearl Harbor, HI 96860–3134.

SUPPLEMENTARY INFORMATION: The Draft Supplemental EIS/OEIS was distributed to federal and local agencies with which the DoN consulted. Copies of the Draft Supplemental EIS/OEIS are available for public review at the following public libraries:

1. Robert F. Kennedy Memorial Library, University of Guam, UOG Station, Mangilao, GU 96923–1871.

2. Nieves M. Flores Memorial Library, 254 Martyr Street, Hagåtña, GU 96910–5141.

3. Tinian Public Library, San Jose Village, Tinian, MP 96952–9997.

4. Antonio C. Atalig Memorial Library (Rota Public Library), Rota, MP 96951–9997.

5. Joeten-Kiyu Public Library, Insatto Street, Saipan, MP 96950–9996.

The MITT Draft Supplemental EIS/OEIS is available for electronic viewing or download at *www.MITT-EIS.com*. A compact disc of the Draft Supplemental EIS/OEIS will be made available upon written request by contacting: Naval Facilities Engineering Command Pacific, Attention: MITT Supplemental EIS/OEIS Project Manager, 258 Makalapa Drive, Suite 100, Pearl Harbor, HI 96860–3134.

Dated: January 25, 2019.

M.S. Werner,

Commander, Judge Advocate General's Corps, U.S. Navy, Federal Register Liaison Officer.

DEPARTMENT OF DEFENSE

Department of the Navy

Notice of Availability of the Record of Decision for the Final Supplemental Environmental Impact Statement for Land-Water Interface and Service Pier Extension at Naval Base Kitsap Bangor, Kitsap County, WA

AGENCY: Department of the Navy, DoD.

ACTION: Notice.

SUMMARY: The United States Department of the Navy (Navy), announces its decision to construct and operate a Service Pier Extension (SPE) and associated support facilities in Hood Canal on the waterfront of Naval Base (NAVBASE) Kitsap Bangor, Washington (WA). The Navy will implement Alternative 2, short pier configuration, which is the preferred alternative in the October 2018 Final Supplemental Environmental Impact Statement (SEIS) for the Land-Water Interface (LWI) and SPE, NAVBASE Kitsap Bangor, WA. The Alternative 2 short pier configuration is also the environmentally preferred alternative and will fully meet the Navy's purpose and need for the proposed action.

SUPPLEMENTARY INFORMATION: The existing Service Pier will be extended by 520 feet and will require in-water as well as upland construction of

FARM CREDIT SYSTEM INSURANCE CORPORATION

Regular Meeting; Farm Credit System Insurance Corporation Board

AGENCY: Farm Credit System Insurance Corporation.

ACTION: Notice, regular meeting.

SUMMARY: Notice is hereby given of the regular meeting of the Farm Credit System Insurance Corporation Board (Board).

DATES: The meeting of the Board will be held at the offices of the Farm Credit Administration in McLean, Virginia, on January 17, 2019, from 2:00 p.m. until such time as the Board concludes its business.

ADDRESSES: Farm Credit System Insurance Corporation, 1501 Farm Credit Drive, McLean, Virginia 22102. Submit attendance requests via email to *VisitorRequest@FCA.gov.* See **SUPPLEMENTARY INFORMATION** for further information about attendance requests.

FOR FURTHER INFORMATION CONTACT: Dale Aultman, Secretary to the Farm Credit System Insurance Corporation Board, (703) 883–4009, TTY (703) 883–4056, *aultmand@fca.gov.*

SUPPLEMENTARY INFORMATION: Parts of this meeting of the Board will be open to the public (limited space available), and parts will be closed to the public. Please send an email to *VisitorRequest@FCA.gov* at least 24 hours before the meeting. In your email include: Name, postal address, entity you are representing (if applicable), and telephone number. You will receive an email confirmation from us. Please be prepared to show a photo identification when you arrive. If you need assistance for accessibility reasons, or if you have any questions, contact Dale Aultman, Secretary to the Farm Credit System Insurance Corporation Board, at (703) 883–4009. The matters to be considered at the meeting are:

Open Session

A. Approval of Minutes

- December 13, 2018

B. New Business

- Review of Insurance Premium Rates

[1] See the *Notice of Technical Conference* issued on December 12, 2018, for additional details regarding this conference.

DEPARTMENT OF DEFENSE

Office of the Secretary

[Docket ID: DOD–2018–OS–0104]

Submission for OMB Review; Comment Request

AGENCY: Office of the Secretary of Defense, DoD.

ACTION: 30-Day information collection notice.

SUMMARY: The Department of Defense has submitted to OMB for clearance the following proposal for collection of information under the provisions of the Paperwork Reduction Act.

DATES: Consideration will be given to all comments received by April 8, 2019.

ADDRESSES: Comments and recommendations on the proposed information collection should be emailed to Ms. Jasmeet Seehra, DoD Desk Officer, at *oira_submission@omb.eop.gov*. Please identify the proposed information collection by DoD Desk Officer, Docket ID number, and title of the information collection.

FOR FURTHER INFORMATION CONTACT: Angela James, 571–372–7574, or *whs.mc-alex.esd.mbx.dd-dod-information-collections@mail.mil*.

SUPPLEMENTARY INFORMATION:

Title; Associated Form; and OMB Number: Vietnam War Commemoration Program Partner Events; DD Form 2953; DD Form 2954; DD Form 3027; DD Form 3028; DD Form 3029; OMB Control Number 0704–0500.

Type of Request: Extension.

Number of Respondents: 16,020.

Responses per Respondent: 1.8739.

Annual Responses: 30,020.

Average Burden per Response: 15 minutes.

Annual Burden Hours: 7,505.

Needs and Uses: This information collection requirement is necessary to notify the United States of America Vietnam War Commemoration Program of Commemorative Partner's planned events. Information is submitted for inclusion on the program's events calendar and to request event support in the form of materials and/or speakers from the program. The information collection is necessary to obtain, vet, record, process and provide Certificates of Honor to be presented on behalf of a grateful nation by partner organizations. Additionally, this collection is necessary for the partner organizations to communicate to the Commemoration program the results of their events and lessons learned.

Affected Public: Businesses or other for-profits; Not-for-profit institutions; Federal Government; State, local or tribal government, or, by exception, eligible individuals or households.

Frequency: On occasion.

Respondent's Obligation: Voluntary.

OMB Desk Officer: Ms. Jasmeet Seehra.

You may also submit comments and recommendations, identified by Docket ID number and title, by the following method:

- *Federal eRulemaking Portal: http://www.regulations.gov*. Follow the instructions for submitting comments.

Instructions: All submissions received must include the agency name, Docket ID number, and title for this **Federal Register** document. The general policy for comments and other submissions from members of the public is to make these submissions available for public viewing on the internet at *http://www.regulations.gov* as they are received without change, including any personal identifiers or contact information.

DOD Clearance Officer: Ms. Angela James.

Requests for copies of the information collection proposal should be sent to Ms. James at *whs.mc-alex.esd.mbx.dd-dod-information-collections@mail.mil*.

Dated: March 4, 2019.

Aaron T. Siegel,

Alternate OSD Federal Register Liaison Officer, Department of Defense.

DEPARTMENT OF DEFENSE

Department of the Navy

Notice of Rescheduled Public Meetings and Extension of Public Comment Period for the Draft Supplemental Environmental Impact Statement/ Overseas Environmental Impact Statement for Mariana Islands Training and Testing

AGENCY: Department of the Navy, DoD.

ACTION: Notice.

SUMMARY: A notice of public meetings was published in the **Federal Register** by the U.S. Environmental Protection Agency on January 31, 2019 for the Department of the Navy's (DoN) Draft Supplemental Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS) for the Mariana Islands Training and Testing (MITT) Study Area. Due to the effects of Typhoon Wutip, Navy officials postponed public meetings supporting the Draft Supplemental EIS/OEIS planned for February 26–27, 2019.

DATES: This notice announces the dates and locations of the rescheduled public meetings in March 2019, and a 15-day extension of the public comment period from March 18, 2019, to April 2, 2019.

ADDRESSES: Public meetings will be held in an open-house format with DoN representatives available to provide information and answer questions related to the Draft Supplemental EIS/OEIS. The public may arrive at any time during meetings, as there will not be a presentation or public oral comment session. Open house public meetings will be held on the following dates and at the following locations:

1. 1:00 to 3:30 p.m. March 14, 2019, at Tinian Public Library, San Jose Village, Tinian, MP 96952.
2. 1:30 to 4:30 p.m. March 15, 2019, at Mayor's Conference Hall, Songsong Village, Rota, MP 96951.
3. 5:00 to 8:00 p.m. March 18, 2019, at Kanoa Resort Saipan, Seaside Hall, Beach Road in Susupe, Saipan, MP 96950.
4. 5:00 to 8:00 p.m. March 19, 2019, at University of Guam, Jesus & Eugenia Leon Guerrero School of Business and Public Administration Building, Anthony Leon Guerrero Multi-Purpose Room 129 and Henry Sy Atrium, Mangilao, Guam 96923.

Attendees will be able to submit comments during the open house public meetings. Comments may also be mailed to Naval Facilities Engineering Command Pacific, Attention: MITT Supplemental EIS/OEIS Project Manager, 258 Makalapa Drive, Suite 100, Pearl Harbor, HI 96860–3134, or electronically via the project website at *www.MITT-EIS.com*. All comments submitted during the public comment period will become part of the public record and substantive comments will be addressed in the Final Supplemental EIS/OEIS. All comments must be postmarked or received online by April 2, 2019, Chamorro Standard Time, for consideration in the Final Supplemental EIS/OEIS.

Naval Facilities Engineering Command Pacific, Attention: MITT Supplemental EIS/OEIS Project Manager, 258 Makalapa Drive, Suite 100, Pearl Harbor, HI 96860–3134.

SUPPLEMENTARY INFORMATION: The Draft Supplemental EIS/OEIS is available

Figure 8.3-3: Federal Register Notice of Rescheduled Public Meetings for the Draft SEIS/OEIS

electronically for public viewing at *www.MITT-EIS.com* and at the following public libraries:

AGENCY: Department of the Navy, DoD.

ACTION: Notice.

SUMMARY: The Department of the Navy hereby gives notice of its intent to grant to Nanocrine, Inc., of Frederick, Maryland an exclusive license in the field of use of products and services for use in cell biology research for cell signaling and phenotyping studies and the field of use of products and services for use in cell biology research for cell protein and chemical secretion, in the United States, to U.S. Patent 9,791,368: Nanoplasmonic Imaging Technique for the Spatio-temporal Mapping of Single Cell Secretions in Real Time, Navy Case No. 102,395.//U.S. Patent Application No. 15/784,433: Nanoplasmonic Imaging Technique for the Spatio-Temporal Mapping of Single Cell Secretion in Real Time, Navy Case No. 102,395.//U.S. Patent No. 9,915,654: Light Microscopy Chips and Data Analysis Methodology for Quantitative Localized Surface Plasmon Resonance (LSPR) Biosensing and Imaging, Navy Case No. 101,529.//U.S. Patent Application No. 15/882,081: Light Microscopy Chips and Data Analysis Methodology for Quantitative Localized Surface Plasmon Resonance (LSPR) Biosensing and Imaging, Navy Case No. 101,529.//U.S Patent Application No. 14/039,326: Calibrating Single Plasmonic Nanostructures for Quantitative Biosensing, Navy Case No. 102,043.//U.S Patent Application No. 15/186,742: Determining Extracellular Protein Concentration with Nanoplasmonic Sensors, Navy Case No. 103,502.//U.S. Patent Application No. 16/196,097: Substrates with Indendently Tunable Topographies and Chemistries for Quantifying Surface-Induced Cell Behavior, Navy Case No. 107,399 and any continuations, divisionals, or re-issues thereof.

DATES: Anyone wishing to object to the grant of this license must file written objections along with supporting evidence, if any, not later than March 25, 2019.

ADDRESSES: Written objections are to be filed with the Naval Research Laboratory, Code 1004, 4555 Overlook Avenue SW, Washington, DC 20375–5320.

FOR FURTHER INFORMATION CONTACT: Amanda Horansky McKinney, Head, Technology Transfer Office, NRL Code 1004, 4555 Overlook Avenue SW, Washington, DC 20375–5320, telephone 202–767–1644. Due to U.S. Postal delays, please fax 202–404–7920, email: *techtran@.nrl.navy.mil* or use courier delivery to expedite response.

(Authority: 35 U.S.C. 207, 37 CFR part 404.)

M.S. Werner,

Commander, Judge Advocate General's Corps, U.S. Navy, Federal Register Liaison Officer.

BILLING CODE 3810–FF–P

DEPARTMENT OF ENERGY

Energy Conservation Program for Consumer Products: Representative Average Unit Costs of Energy

AGENCY: Office of Energy Efficiency and Renewable Energy, Department of Energy.

ACTION: Notice.

SUMMARY: In this notice, the U.S. Department of Energy (DOE) is forecasting the representative average unit costs of five residential energy sources for the year 2019 pursuant to the Energy Policy and Conservation Act (Act). The five sources are electricity, natural gas, No. 2 heating oil, propane, and kerosene.

DATES: The representative average unit costs of energy contained in this notice will become effective April 8, 2019 and will remain in effect until further notice.

FOR FURTHER INFORMATION CONTACT: John Cymbalsky, U.S. Department of Energy, Office of Energy Efficiency and Renewable Energy Forrestal Building, Mail Station EE–5B, 1000 Independence Avenue SW, Washington, DC 20585–0121, (202) 287–1692, *ApplianceStandardsQuestions@ee.doe.gov.*

Francine Pinto, Esq. U.S. Department of Energy, Office of General Counsel Forrestal Building, Mail Station GC–33, 1000 Independence Avenue SW, Washington, DC 20585–0103, (202) 586–7432, *Francine.Pinto@hq.doe.gov.*

SUPPLEMENTARY INFORMATION: Section 323 of the Energy Policy and Conservation Act requires that DOE prescribe test procedures for the measurement of the estimated annual operating costs or other measures of energy consumption for certain consumer products specified in the Act. (42 U.S.C. 6293(b)(3)) These test procedures are found in Title 10 of the Code of Federal Regulations (CFR) part 430, subpart B.

Section 323(b)(3) of the Act requires that the estimated annual operating costs of a covered product be calculated from measurements of energy use in a representative average use cycle or period of use and from representative average unit costs of the energy needed to operate such product during such cycle. (42 U.S.C. 6293(b)(3)) The section further requires that DOE provide information to manufacturers regarding the representative average unit costs of energy. (42 U.S.C. 6293(b)(4)) This cost information should be used by manufacturers to meet their obligations under section 323(c) of the Act. Most notably, these costs are used to comply with Federal Trade Commission (FTC) requirements for labeling. Manufacturers are required to use the revised DOE representative average unit costs when the FTC publishes new ranges of comparability for specific covered products, 16 CFR part 305. Interested parties can also find information covering the FTC labeling requirements at *http://www.ftc.gov/appliances.*

DOE last published representative average unit costs of residential energy in a **Federal Register** notice entitled, "Energy Conservation Program for Consumer Products: Representative Average Unit Costs of Energy", dated April 24, 2018, 83 FR 17811.

On April 8, 2019, the cost figures published in this notice will become effective and supersede those cost figures published on April 24, 2018. The cost figures set forth in this notice will be effective until further notice.

DOE's Energy Information Administration (EIA) has developed the 2019 representative average unit after-tax residential costs found in this notice. These costs for electricity,

Figure 8.3-3: Federal Register Notice of Rescheduled Public Meetings for the Draft SEIS/OEIS (continued)

and Recreation Department, Oregon Department of Environmental Quality, Oregon Department of Land Conservation and Development, Oregon Department of State Lands, and Oregon Department of Agriculture.

Alternatives. The EIS will evaluate a no action alternative and action alternatives. The no action alternative is the current management direction for the WVS. Action alternatives will be composed of various measures for continued operations and maintenance of the WVS, as well as measures that will be developed to meet ESA obligations to avoid jeopardizing the continued existence of listed species. Comments received during the scoping comment period will inform the development of action alternatives.

Scoping Process/Public Involvement. The Corps invites all affected federal, state, and local agencies, affected Native American Tribes, other interested parties, and the general public to participate in the NEPA process during development of the EIS. The purpose of the public scoping process is to provide information to the public, narrow the scope of analysis to significant environmental issues, serve as a mechanism to solicit agency and public input on alternatives and issues of concern, and ensure full and open participation in scoping for the Draft EIS. Numerous public scoping meetings will be held during the scoping period. The specific dates, times, and locations of the meetings will be published on the Corps' project website: *https://www.nwp.usace.army.mil/Locations/Willamette-Valley/Evaluation/.*

This is not a notice for the public comment periods for the Cougar Downstream Passage and Detroit Downstream Passage projects; public comment periods for those projects will be noticed separately.

Documents and other important information related to the EIS will be available for review on the Corps' project website.

Aaron L. Dorf,
Colonel, Corps of Engineers, District Commander.

DEPARTMENT OF DEFENSE

Department of the Navy

Notice of Availability of Government-Owned Inventions; Available for Licensing

AGENCY: Department of the Navy, DoD.

ACTION: Notice.

SUMMARY: The Department of the Navy (DoN) announces the availability of the inventions listed below, assigned to the United States Government, as represented by the Secretary of the Navy, for domestic and foreign licensing by the Department of the Navy.

ADDRESSES: Requests for copies of the patents cited should be directed to Naval Surface Warfare Center, Crane Div, Code OOL, Bldg 2, 300 Highway 361, Crane, IN 47522–5001.

FOR FURTHER INFORMATION CONTACT: Mr. Christopher Monsey, Naval Surface Warfare Center, Crane Div, Code OOL, Bldg 2, 300 Highway 361, Crane, IN 47522–5001, Email *Christopher.Monsey@navy.mil*, 812–854–2777.

SUPPLEMENTARY INFORMATION: The following patents are available for licensing: Patent No. 10,200,081 (Navy Case No. 200348): SYSTEMS AND METHODS FOR SIGNAL DETECTION AND DIGITAL BANDWIDTH REDUCTION IN DIGITAL PHASED ARRAYS// Patent No. 10,204,875 (Navy Case No. 200421): SYSTEMS AND METHODS FOR INHIBITING BACKEND ACCESS TO INTEGRATED CIRCUITS BY INTEGRATING PHOTON AND ELECTRON SENSING LATCH-UP CIRCUITS// Patent No. 10,209,342 (Navy Case No. 200479): ELECTROMAGNETIC RADIATION SOURCE LOCATING SYSTEM// and Patent No. 10,215,531 (Navy Case No. 200357): TESTING SYSTEM FOR OPTICAL AIMING SYSTEMS WITH LIGHT EMITTER SYSTEMS INCLUDING TESTING SYSTEM FOR THERMAL DRIFT AND RELATED METHODS.

Authority: 35 U.S.C. 207, 37 CFR part 404.

Dated: March 26, 2019.

M.S. Werner,
Commander, Judge Advocate General's Corps, U.S. Navy, Federal Register Liaison Officer.

Department of the Navy

Notice of Extension of Public Comment Period for the Draft Supplemental Environmental Impact Statement/Overseas Environmental Impact Statement for Mariana Islands Training and Testing

AGENCY: Department of the Navy, DoD.

ACTION: Notice.

SUMMARY: A notice of public meetings was published in the **Federal Register** by the U.S. Environmental Protection Agency on January 31, 2019 and March 8, 2019 for the Department of the Navy's (DoN) Draft Supplemental Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS) for the Mariana Islands Training and Testing (MITT) Study Area.

DATES: This notice announces a 15-day extension of the public comment period from April 2, 2019, to April 17, 2019.

ADDRESSES: Comments may be mailed to Naval Facilities Engineering Command Pacific, Attention: MITT Supplemental EIS/OEIS Project Manager, 258 Makalapa Drive, Suite 100, Pearl Harbor, HI 96860–3134, or electronically via the project website at *www.MITT-EIS.com*. All comments submitted during the public comment period will become part of the public record and substantive comments will be addressed in the Final Supplemental EIS/OEIS. All comments must be postmarked or received online by April 17, 2019, Chamorro Standard Time, for consideration in the Final Supplemental EIS/OEIS.

Naval Facilities Engineering Command Pacific, Attention: MITT Supplemental EIS/OEIS Project Manager, 258 Makalapa Drive, Suite 100, Pearl Harbor, HI 96860–3134.

SUPPLEMENTARY INFORMATION: The Draft Supplemental EIS/OEIS is available electronically for public viewing at *www.MITT-EIS.com* and at the following public libraries:

1. Robert F. Kennedy Memorial Library, University of Guam, UOG Station, Mangilao, GU 96923–1871.

2. Nieves M. Flores Memorial Library, 254 Martyr St., Hagåtña, GU 96910–5141.

3. Tinian Public Library, San Jose Village, Tinian, MP 96952–9997.

4. Antonio C. Atalig Memorial Library (Rota Public Library), Rota, MP 96951–9997.

5. Joeten-Kiyu Public Library, Beach Road and Insatto St., Saipan, MP 96950–9996.

Dated: March 25, 2019.

8.3.1 Notification of Draft Supplemental Environmental Impact Statement/Overseas Environmental Impact Statement Public Review and Comment Period and Public Meetings

The Navy made significant efforts to notify the public of the release of the Draft SEIS/OEIS and the dates and locations of the public meetings to maximize participation during the Draft SEIS/OEIS public review and comment period. A summary of these efforts follows.

8.3.1.1 Notification Letters

Stakeholder letters were mailed January 30, 2019, first-class to 218 federal and local elected officials and agency representatives. Entities that received the notification letters are listed in Table 8.3-1, and Figure 8.3-5 provides an example of the notification letter.

DEPARTMENT OF THE NAVY
COMMANDER
UNITED STATES PACIFIC FLEET
250 MAKALAPA DRIVE
PEARL HARBOR, HAWAII 96860-3131

IN REPLY REFER TO:
5090
Ser N465/0059
January 14, 2019

The Honorable Vinnie V. Sablan
Senator, Saipan
CNMI Senate
P.O. Box 500129
Saipan, MP 96950

Dear Senator Sablan:

SUBJECT: NOTICE OF AVAILABILITY OF THE MARIANA ISLANDS TRAINING AND TESTING DRAFT SUPPLEMENTAL ENVIRONMENTAL IMPACT STATEMENT/OVERSEAS ENVIRONMENTAL IMPACT STATEMENT

This letter is to inform you that the Department of the Navy (Navy) has prepared a draft supplement to the 2015 Final Mariana Islands Training and Testing (MITT) Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS) to assess the potential environmental impacts associated with ongoing at-sea and Farallon de Medinilla (FDM) military readiness activities conducted within the MITT EIS/OEIS Study Area (hereafter referred to as the "Study Area"). Military readiness activities include training and research, development, testing, and evaluation activities (hereafter referred to as "training and testing"). The Navy welcomes your review and comments on the Draft Supplemental EIS/OEIS.

In May 2015, the Navy completed an EIS/OEIS for training and testing activities occurring within the Study Area from 2015 through 2020. The supplement to the 2015 MITT Final EIS/OEIS supports ongoing and future activities conducted within the Study Area at sea and on FDM. The proposed activities are generally consistent with those analyzed in the 2015 MITT Final EIS/OEIS and are representative of activities the military has conducted in the Study Area for decades.

In the Draft Supplemental EIS/OEIS, the Navy evaluates new, relevant information, such as more recent marine mammal density data and new scientific information, and updates the environmental analyses as appropriate. The Navy prepared the Draft Supplemental EIS/OEIS to support the issuance of federal regulatory permits and authorizations under the Marine Mammal Protection Act and the Endangered Species Act.

The Study Area remains unchanged since the 2015 MITT Final EIS/OEIS. The Study Area includes the existing Mariana Islands Range Complex (MIRC), additional areas on the high seas outside of the MIRC, a transit corridor between the MIRC and the Hawaii Range Complex, and

Figure 8.3-5: Stakeholder Letter for the Notification of Availability of the Draft SEIS/OEIS

5090
Ser N465/0059
January 14, 2019

Navy piers located in Apra Harbor (Enclosure 1). Other activities and land components associated with the MIRC (except FDM) are not considered in the supplement.

The Proposed Action is to conduct at-sea training and testing activities within the Study Area. These activities include the use of active sonar and explosives while employing marine species mitigation measures. The purpose of the Proposed Action is to conduct training and testing activities to ensure that the Navy and other U.S. military services meet their respective missions, which, for the Navy is to maintain, train, and equip combat-ready forces capable of winning wars, deterring aggression, and maintaining freedom of the seas, consistent with Congressional direction in Section 5062 of Title 10 of the U.S. Code.

To achieve and maintain military readiness, the Navy proposes to:

- Conduct at-sea training and testing activities at levels required to support military readiness requirements beyond 2020; and
- Accommodate evolving mission requirements, including those resulting from the development, testing, and introduction of new vessels, aircraft, and weapons systems into the fleet.

The Navy will hold two open house public meetings to provide information, answer questions, and give the public an opportunity to comment on the Draft Supplemental EIS/OEIS. The public may arrive at any time between 5 to 8 p.m., as there will not be a presentation or formal oral comment session. The meeting will be held at the following locations:

Guam:

Date: **Tuesday, February 26, 2019**
Location: University of Guam
Jesus & Eugenia Leon Guerrero School of Business and Public Administration Building
Anthony Leon Guerrero Multi-Purpose Room 129 and Henry Sy Atrium
Mangilao, Guam 96923

Saipan:

Date: **Wednesday, February 27, 2019**
Location: Kanoa Resort Saipan
Seaside Hall
Beach Road in Susupe
Saipan, MP 96950

To review the Draft Supplemental EIS/OEIS and for additional information, including details on the key differences between the 2015 MITT Final EIS/OEIS and the 2019 Draft Supplemental EIS/OEIS, please visit the project website at **www.MITT-EIS.com**. The Draft Supplemental EIS/OEIS is also available at the following local public libraries:

8.3.1.2 Postcard Mailers

Postcards were mailed January 30, 2019, first-class from Guam to 350 recipients on the project mailing list, including individuals; nongovernmental organizations; community and business groups; fishing, aviation, and recreation groups; and private companies. A second postcard mailer announcing the rescheduled public meeting information and the 15-day extension of the public review and comment period was mailed first-class March 6, 2019, to 568 recipients, including federal and local elected officials and agency representatives, individuals, community and business groups, nongovernmental organizations, and media. The postcards included the dates, locations, and times of the public meetings, as well as the project website address for more information, commenting information, and a brief summary of the Proposed Action. The postcard mailers are shown in Figure 8.3-6 and Figure 8.3-7.

8.3.1.3 Newspaper Advertisements

Display advertisements were published in three local and regional newspapers announcing the Notice of Availability/Notice of Public Meetings beginning February 1, 2019, through February 26, 2019. A display advertisement announcing the rescheduled public meetings was published March 7, 2019, through March 18, 2019. An additional display advertisement announcing the public comment extension period was published April 1, 2019, through April 3, 2019. The advertisements included a brief description of the Proposed Action, the project website address, the duration of the comment period, and information on how to provide comments. The newspapers and publication dates are indicated in Table 8.3-2. Examples of the advertisements are shown in Figure 8.3-8, Figure 8.3-9, and Figure 8.3-10.

Figure 8.3-8: Newspaper Announcement of the Draft SEIS/OEIS Availability and Public Meetings

The U.S. Navy
INVITES YOU TO PARTICIPATE
in the Mariana Islands Training and Testing
Supplemental EIS/OEIS Public Involvement Process

Due to the effects of Typhoon Wutip, Navy officials postponed public meetings planned for Feb. 26-27, 2019. This notice announces the rescheduled public meetings and a 15-day extension of the comment period.

The U.S. Navy has prepared a Draft Supplemental Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS) to assess the potential environmental impacts associated with ongoing military readiness activities conducted within the Mariana Islands Training and Testing (MITT) EIS/OEIS Study Area. The draft supplement to the 2015 MITT Final EIS/OEIS supports ongoing and future activities conducted within the Study Area: at sea and on Farallon de Medinilla (FDM).

Public Involvement

The Navy welcomes your review and comments on the Draft Supplemental EIS/OEIS. Comments may be submitted at the public meetings, online at **www.MITT-EIS.com**, or by mail to:

Naval Facilities Engineering Command Pacific
Attention: MITT SEIS/OEIS Project Manager
258 Makalapa Drive, Suite 100
Pearl Harbor, HI 96860-3134

Comments must be postmarked or received online by April 2, 2019, Chamorro Standard Time, for consideration in the Final Supplemental EIS/OEIS.

Open House Public Meetings

Arrive and submit comments anytime during the open house. No presentation or public oral comment session will be conducted.

Public Comment Period Extended for the Mariana Islands Training and Testing Draft Supplemental EIS/OEIS

The U.S. Navy has extended the public comment period by an additional 15 days for the Mariana Islands Training and Testing (MITT) Draft Supplemental Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS). Public comments may now be submitted until **April 17, 2019**, for consideration in the Final Supplemental EIS/OEIS.

The U.S. Navy has prepared a Draft Supplemental EIS/OEIS to assess the potential environmental impacts associated with ongoing military readiness activities conducted within the MITT EIS/OEIS Study Area. The draft supplement to the 2015 Final MITT EIS/OEIS supports ongoing and future activities conducted within the Study Area: at sea and on Farallon de Medinilla (FDM).

PUBLIC INVOLVEMENT

The Navy welcomes your review and comments on the Draft Supplemental EIS/OEIS.
Comments will be accepted online at **www.MITT-EIS.com** or by mail to:

Naval Facilities Engineering Command Pacific
Attention: MITT Supplemental EIS/OEIS Project Manager
258 Makalapa Drive, Suite 100
Pearl Harbor, HI 96860-3134

All comments must be postmarked or received online by April 17, 2019, Chamorro Standard Time, for consideration in the Final Supplemental EIS/OEIS.

The draft document is available online at **www.MITT-EIS.com** or at the following public libraries: University of Guam Robert F. Kennedy Memorial Library, Nieves M. Flores Memorial Library, Joeten-Kiyu Public Library, Tinian Public Library, and Rota Public Library.

8.3.1.4 Press Releases

Commander, Joint Region Marianas Public Affairs Office distributed press releases to local and regional media outlets February 4, 2019; March 6, 2019; and March 28, 2019. The press releases provided a description of the Proposed Action; address of the project website; duration of the comment period and commenting methods; location of the information repositories; and location, dates, and times of the public meetings. The press releases provided information on the availability of the Navy to meet with the media in advance of the meetings. The press releases from the Commander, Joint Region Marianas are shown in Figure 8.3-11, Figure 8.3-12, and Figure 8.3-13.

FOR IMMEDIATE RELEASE
Press Release 19-012

Mariana Islands Training and Testing Draft SEIS/OEIS Available for Public Review and Comment

ASAN, Guam (Feb. 4, 2019) – The U.S. Navy has prepared a draft supplement to the 2015 Final Mariana Islands Training and Testing (MITT) Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS).

In the Draft Supplemental EIS/OEIS, the Navy evaluates the potential environmental impacts associated with conducting ongoing and future military readiness activities within the Study Area at sea and on Farallon de Medinilla.

The Navy requests and welcomes substantive public comments on the MITT Draft Supplemental EIS/OEIS.

PROPOSED ACTION:

The Proposed Action is to conduct at-sea training and testing activities within the Study Area. These activities include the use of active sonar and explosives while employing marine species mitigation measures. The purpose of the Proposed Action, which remains the same as the 2015 MITT Final EIS/OEIS, is to maintain a ready force to ensure the military can accomplish its mission to maintain, train, and equip combat-ready forces.

The proposed at-sea training and testing activities are generally consistent with those analyzed in the 2015 MITT Final EIS/OEIS and are similar to activities the military has conducted in the Study Area for decades.

The MITT Study Area includes:

- The Mariana Islands Range Complex
- Areas on the high seas to the north and west of the Mariana Islands Range Complex
- A transit corridor between the Mariana Islands Range Complex and the Hawaii Range Complex, starting at the International Date Line
- Apra Harbor and select Navy pierside and harbor locations

The Study Area has not changed since the 2015 Final EIS/OEIS. In the Supplemental EIS/OEIS, the Navy analyzes only the training and testing activities conducted at sea and on FDM within the

Mariana Islands Training and Testing Supplemental EIS/OEIS

Study Area. Other activities and land areas are not included and remain covered under the 2015 analysis and associated authorizations.
Please visit the project website at **www.MITT-EIS.com** to download the Draft Supplemental EIS/OEIS and submit substantive comments online.

AVAILABILITY OF DRAFT SUPPLEMENTAL EIS/OEIS AND PUBLIC COMMENT PERIOD:

The Navy is seeking public review and comment on the Proposed Action and alternatives and the accuracy and adequacy of the environmental analysis. The Draft Supplemental EIS/OEIS is available for public review online at **www.MITT-EIS.com** and at the following locations:

GUAM
Robert F. Kennedy Memorial Library
University of Guam
UOG Station
Mangilao, GU 96923

Nieves M. Flores Memorial Library
254 Martyr St.
Hagåtña, GU 96910

SAIPAN
Joeten-Kiyu Public Library
Beach Road and Insatto St.
Saipan, MP 96950

TINIAN
Tinian Public Library
San Jose Village
Tinian, MP 96952

ROTA
Antonio C. Atalig Memorial Library
Rota, MP 96951

The Navy will accept comments throughout the public comment period, which ends March 18. All comments must be postmarked or received online by **March 18, 2019**, Chamorro Standard Time, for consideration in the Final Supplemental EIS/OEIS. Comments may be submitted online at **www.MITT-EIS.com**, at the public meetings, or by mail to:

Naval Facilities Engineering Command Pacific
Attention: MITT Supplemental EIS/OEIS Project Manager
258 Makalapa Drive, Suite 100
Pearl Harbor, HI 96860-3134

OPEN HOUSE PUBLIC MEETINGS:

The Navy will hold two open house public meetings to provide information, answer questions, and give the public an opportunity to comment on the Draft Supplemental EIS/OEIS. The public may arrive at any time between 5-8 p.m., as there will not be a presentation or formal oral comment session. The meetings will be held at the following locations:

GUAM
Date: **Tuesday, Feb. 26**
Location: University of Guam

FOR IMMEDIATE RELEASE
Press Release 19-023

MITT Draft SEIS/OEIS Public Comment Period Extended, Public Meetings Announced

SANTA RITA, Guam (March 6, 2019) – The U.S. Navy invites the public to attend open house public meetings for the Mariana Islands Training and Testing Draft Supplemental Environmental Impact Statement/Overseas Environmental Impact Statement.

Due to the effects of Typhoon Wutip, Navy officials postponed public meetings supporting the Draft Supplemental EIS/OEIS planned for Feb. 26-27. Rescheduled public meeting dates and locations are listed below.

The public comment period has been extended by 15 days from March 18 to **April 2**. The Navy will host separate meetings on Guam and in the CNMI in compliance with Section 106 of the National Historic Preservation Act to specifically focus on effects to historic properties. The purpose of the section 106 meetings are to engage with existing consulting parties.

In the Draft Supplemental EIS/OEIS, the Navy evaluates the potential environmental impacts associated with ongoing and future military readiness activities conducted within the Study Area at sea and on Farallon de Medinilla. The Navy requests and welcomes substantive public comments on the Draft Supplemental EIS/OEIS.

OPEN HOUSE PUBLIC MEETINGS:

The Navy will hold four open house public meetings to provide information, answer questions, and give the public an opportunity to comment on the Draft Supplemental EIS/OEIS. The public may arrive at any time during the meetings, as there will not be a presentation or public oral comment session. The meetings will be held at the following locations:

TINIAN
Date: **Thursday, March 14, 1-3:30 p.m.**
Location: Tinian Public Library
San Jose Village
Tinian, MP

8.3.1.5 Subscriber Email Notifications

Project information was also distributed via the project website subscriber's email distribution list. Website subscribers from the scoping phase were carried forward into the Draft SEIS/OEIS phase, beginning with 24 initial website subscribers. An email notification was sent to website subscribers on February 1, 2019, to announce the availability of the Draft SEIS/OEIS for review and comment and public meetings. A second email was sent on March 6, 2019, announcing the rescheduled public meetings and 15-day extended public comment and review period. A third email was sent on March 27, 2019, announcing an additional 15-day public comment period extension. As of September 2019, there are 48 website subscribers.

8.3.2 Public Meetings

The Navy held four public meetings to inform the public about the Proposed Action and to solicit public comments on the Draft SEIS/OEIS. The public meetings included informational poster and video stations staffed by Navy representatives. A stenographer was available to transcribe one-on-one oral comments; written comments were submitted at any time during the meetings. Members of the public could arrive at any time during the public meetings, which were held from 5:00 to 8:00 p.m. In total, 109 people attended the four meetings. The public meeting locations and dates are shown in Table 8.3-3.

Table 8.3-3: Public Meeting Locations

Area Location	Meeting Venue	Date
Tinian	Tinian Public Library	Thursday, March 14, 2019
Rota	Mayor's Conference Hall	Friday, March 15, 2019
Saipan	Kanoa Resort Saipan Seaside Hall	Monday, March 18, 2019
Guam	University of Guam Multipurpose Room	Tuesday, March 19, 2019

8.4 Comments on the Draft Supplemental Environmental Impact Statement/Overseas Environmental Impact Statement

Throughout the public comment period, a total of 318 unique comments were received. Public comments on the Draft SEIS/OEIS were submitted in three ways:

- Written letters (received any time during the public comment period) (8 comments).
- Comments submitted at a public meeting (written or oral) (written: 7 comments; oral: 0 comments).
- Comments submitted directly on the project website (received any time during the public comment period) (303 comments).

Appendix K (Public Comment Responses) contains the comments received on the Draft SEIS/OEIS and the Navy's responses.

8.5 Distribution of the Draft and Final Supplemental Environmental Impact Statement/Overseas Environmental Impact Statement

All parties notified of the availability of the Draft SEIS/OEIS were directed to view the document electronically on the project website (www.mitt-eis.com) or to access hard and CD/DVD copies as available at the information repositories discussed in Section 8.5.2 (Information Repositories).

Due to the widespread outbreak of respiratory illness from the novel coronavirus disease, designated as COVID-19, and federal and territorial guidance on social distancing resulting in the temporary closure of government offices and public facilities, the Navy mailed flash drives containing the Final SEIS/OEIS to all stakeholders and interested parties on the project mailing list. The Final SEIS/OEIS was also available for viewing on the project website and sent to information repositories.

8.5.1 Federal Agencies

The U.S. Environmental Protection Agency received a hard copy and electronic version (CD/DVD) of the Draft and Final SEIS/OEIS. Regional offices of the U.S. Environmental Protection Agency received electronic versions of the Draft and Final SEIS/OEIS. The National Marine Fisheries Service headquarters office received a hard copy and electronic copy of the Draft and Final SEIS/OEIS.

8.5.2 Information Repositories

The Draft and Final SEIS/OEIS were mailed in hard copy form along with an electronic CD/DVD to the information repository locations shown in Table 8.5-1. For the Final SEIS/OEIS, the public was encouraged to check with the library regarding its hours of operation and the availability of the document, depending on COVID-19 conditions regulating access to public facilities.

APPENDIX A TRAINING AND TESTING ACTIVITIES DESCRIPTIONS

A.1 TRAINING ACTIVITIES

The Navy's training activities are organized generally into eight primary mission areas and a miscellaneous category (Other Training) that includes those activities that do not fall within a primary mission area, but are an essential part of Navy training. In addition, because the Navy conducts a number of activities within larger training exercises, descriptions of those larger exercises are also included here. It is important to note that these larger exercises are comprised entirely of individual activities described in the primary mission areas.

A.1.1 MAJOR TRAINING EXERCISES

A major training exercise is comprised of several "unit level" range exercises conducted by several units operating together while commanded and controlled by a single commander. These exercises typically employ an exercise scenario developed to train and evaluate the strike group in naval tactical tasks. In a major training exercise, most of the operations and activities being directed and coordinated by the strike group commander are identical in nature to the operations conducted during individual, crew, and smaller-unit training events. In a major training exercise, however, these disparate training tasks are conducted in concert, rather than in isolation.

Major training exercises are listed below.

A.1.1.1 Joint Expeditionary Exercise

<table>
<tr><th colspan="4">Major Training Exercises – Medium Integrated Anti-Submarine Warfare</th></tr>
<tr><th colspan="4">Joint Expeditionary Exercise</th></tr>
<tr><td>Short Description</td><td colspan="2">Typically a 10-day exercise that could include a Carrier Strike Group and Expeditionary Strike Group, Marine Expeditionary Units, Army Infantry Units, and Air Force aircraft together in a joint environment that includes planning and execution efforts as well as military training activities at sea, in the air, and ashore.</td><td>Typical Duration
10 days</td></tr>
<tr><td>Long Description</td><td colspan="3">Advanced joint level battle group and expeditionary amphibious warfare exercise designed to create a cohesive Carrier and Expeditionary Strike Group. Typically 15 surface ships, amphibious assault craft, helicopters, maritime patrol aircraft, strike fighter aircraft, two submarines, and various unmanned vehicles.
More than 8,000 personnel may participate and could include the combined assets of a Carrier Strike Group and Expeditionary Strike Group, Marine Expeditionary Units, Army Infantry Units, and Air Force aircraft.</td></tr>
<tr><td>Typical Components</td><td colspan="3">Platforms: Aircraft carrier, amphibious warfare ship, fixed-wing aircraft, rotary-wing aircraft, support craft, surface combatant

Major Training Exercises		
Joint Multi-Strike Group Exercise – Large Integrated Anti-Submarine Warfare		
Explosive Bins	None. Presented in appropriate worksheets for unit-level activities that could be conducted during this exercise.	
Procedural Mitigation Measures	**Acoustic Stressors:** *(Section 5.3.2)* Active sonar	**Physical Disturbance and Strike Stressors:** *(Section 5.3.4)* Vessel movement Towed in-water devices
Assumptions Used for Analysis	All military expended materials, ordnance, and explosive use is included in individual events. Additional activities utilizing sources not listed in the Sonar and Other Transducer Bins section above could be used during this exercise, and details can be found in the worksheets for those explosive events. All acoustic sources which may be used during training and testing activities have been accounted for in the modeling and analysis presented in this SEIS/OEIS.	

A.1.2 AIR WARFARE TRAINING

Air warfare is the primary mission area that addresses combat operations by air and surface forces against hostile aircraft. Navy ships contain an array of modern anti-aircraft weapon systems, including naval guns linked to radar-directed fire-control systems, surface-to-air missile systems, and radar-controlled guns for close-in point defense. Strike/fighter aircraft carry anti-aircraft weapons, including air-to-air missiles and aircraft guns. Air warfare training encompasses events and exercises to train ship and aircraft crews in employment of these weapons systems against simulated threat aircraft or targets. Air warfare training includes surface-to-air gunnery, surface-to-air and air-to-air missile exercises, and aircraft force-on-force combat maneuvers.

A.1.2.1 Air Combat Maneuver

Air Warfare			
Air Combat Maneuver (ACM)			
Short Description	Aircrews engage in flight maneuvers designed to gain a tactical advantage during combat.	**Typical Duration**	1–2 hours
Long Description	Basic flight maneuvers in which fixed-wing aircrew engage in offensive and defensive maneuvering against each other. During air combat maneuver engagements, no ordnance is fired, however, countermeasures such as chaff and flares may be used. These maneuvers typically involve two aircraft; however, based upon the training requirement, air combat maneuver exercises may involve over a dozen aircraft.		
Typical Components	**Platforms:** Fixed-wing aircraft **Targets:** Aircraft targets **Systems being Trained/Tested:** None		
Standard Operating Procedures *(Section 2.3.3)*	Aircraft safety	**Typical Locations**	
		Range Complexes/Testing Ranges: Mariana Islands Training and Testing Study Area, Primary areas: Special Use Airspace	**Bays/Estuaries/Pierside:** None

Air Warfare	
Air Defense Exercise (ADEX)	
Procedural Mitigation Measures	**Physical Disturbance and Strike Stressors:** *(Section 5.3.4)* Vessel movement
Assumptions Used for Analysis	No munitions are fired.

A.1.2.3 Air Intercept Control

Air Warfare				
Air Intercept Control (AIC)				
Short Description	Aircrew and air controllers conduct aircraft intercepts of other aircraft.		**Typical Duration**	1–2 hours
Long Description	Fighter jet aircrews maneuver to defend against threat aircraft. An event involves two or more fighter aircraft.			
Typical Components	**Platforms:** Fixed-wing aircraft **Targets:** Aircraft Targets **Systems being Trained/Tested:** None			
Standard Operating Procedures *(Section 2.3.3)*	Aircraft safety	**Typical Locations**		
		Range Complexes/Testing Ranges: Mariana Islands Training and Testing Study Area, Primary areas: Special Use Airspace	**Bays/Estuaries/Pierside:** None

Sonar and Other Transducer Bins	None			
Explosive Bins	None			
Procedural Mitigation Measures	None			
Assumptions Used for Analysis	No munitions are fired. This activity would occur greater than 12 NM from land (FDM excepted).			

A.1.2.4 Gunnery Exercise Air-to-Air Medium-Caliber

Air Warfare				
Gunnery Exercise Air-to-Air Medium-Caliber (GUNEX A-A)				
Short Description	Fixed-wing aircrews fire medium-caliber guns at air targets.	**Typical Duration**	1–2 hours	
Long Description	Fixed-wing aircrews maneuver aircraft in a gunnery pattern to achieve a weapons firing solution with integrated medium-caliber guns. Typically involves two or more fixed-wing aircraft and a target banner towed by a contract aircraft (e.g., Lear jet). The target banner is recovered after the event.			
Typical Components	**Platforms:** Fixed-wing aircraft **Targets:** Air targets **Systems being Trained/Tested:** None			
Standard Operating Procedures *(Section 2.3.3)*	Aircraft safety Weapons firing safety Target deployment and retrieval safety	**Typical Locations**		
		Range Complexes/Testing Ranges: Mariana Islands Training and Testing Study Area, Primary areas: Special Use Airspace	**Bays/Estuaries/Pierside:** None

Missile Exercise Surface-to-Air (MISSILEX S-A)	
Procedural Mitigation Measures	**Acoustic Stressors** *(Section 5.3.2)* Weapons firing noise **Physical Disturbance and Strike Stressors:** *(Section 5.3.4)* Vessel movement
Assumptions Used for Analysis	Assumes that all surface-to-air missiles are high-explosive. Missile explodes well above surface. All explosive and propellant are consumed. Target typically not destroyed, unmanned drones are recovered when possible. This activity would occur greater than 12 NM from land (FDM excepted).

A.1.3 AMPHIBIOUS WARFARE TRAINING

Amphibious warfare is a type of naval warfare involving the utilization of naval firepower, logistics, and Marine Corps landing forces to project military power ashore. Amphibious warfare encompasses a broad spectrum of activities involving maneuver from the sea to objectives ashore, ranging from reconnaissance or raid missions involving a small unit, to large-scale amphibious operations involving over one thousand Marines and Sailors, and multiple ships and aircraft embarked in a strike group.

Amphibious warfare training includes tasks at increasing levels of complexity, from individual, crew, and small unit events to large task force exercises. Individual and crew training include the operation of amphibious vehicles and naval gunfire support training. Small-unit training activities include shore assaults, boat raids, airfield or port seizures, and reconnaissance. Larger-scale amphibious exercises involve ship-to-shore maneuver, shore bombardment and other naval fire support, and air strike and close air support training.

A.1.3.1 Amphibious Rehearsal, No Landing

<table>
<tr><th colspan="6">Amphibious Warfare</th></tr>
<tr><th colspan="6">Amphibious Rehearsal, No Landing</th></tr>

A.1.4 ANTI-SUBMARINE WARFARE TRAINING

Anti-submarine warfare involves helicopter and maritime patrol aircraft, ships, and submarines. These units operate alone or in combination to locate, track, and neutralize submarines. Controlling the undersea battlespace is a unique naval capability and a vital aspect of sea control. Undersea battlespace dominance requires proficiency in anti-submarine warfare. Every deploying strike group and individual surface combatant must possess this capability.

Various types of active and passive sonar are used by the Navy to determine water depth, and identify, track, and target submarines. Passive sonar "listens" for sound waves by using underwater microphones, called hydrophones, which receive, amplify, and process underwater sounds. No sound is introduced into the water when using passive sonar. Passive sonar can indicate the presence, character, and movement of submarines. However, passive sonar provides only a bearing (direction) to a sound-emitting source; it does not provide an accurate range (distance) to the source. Active sonar is needed to locate objects because active sonar provides both bearing and range to the detected contact (such as an enemy submarine).

The Navy's anti-submarine warfare training plan, including the use of active sonar in at-sea training scenarios, includes multiple levels of training. Individual-level anti-submarine warfare training addresses basic skills such as detection and classification of contacts, distinguishing discrete acoustic signatures including those of ships, submarines, and marine life, and identifying the characteristics, functions, and effects of controlled jamming and evasion devices.

More advanced, integrated anti-submarine warfare training exercises involving active sonar are conducted in coordinated, at-sea operations during training events involving submarines, ships, aircraft, and helicopters. This training integrates the full anti-submarine warfare continuum from detecting and tracking a submarine to attacking a target using either exercise torpedoes or simulated weapons. Training events include detection and tracking exercises against "enemy" submarine contacts; torpedo employment exercises against the target; and exercising command and control tasks in a multi-dimensional battlespace.

A.1.4.1 Torpedo Exercise – Helicopter

Anti-Submarine Warfare			
Anti-Submarine Warfare Torpedo Exercise – Helicopter (TORPEX)			
Short Description	Helicopter crews search for, track, and detect submarines. Recoverable air launched torpedoes are employed against submarine targets.	**Typical Duration**	2–5 hours
Long Description	Helicopters using sonobuoys and dipping sonar search for, detect, classify, localize, and track a simulated threat submarine with the goal of determining a firing solution that could be used to launch a torpedo and destroy the submarine. The exercise may be conducted on a portable underwater tracking range. Sonobuoys (both passive and active) are typically employed by a helicopter operating at altitudes below 3,000 feet (ft.). Dipping sonar (both passive and active) is employed from an altitude of about 50 ft. after the search area has been narrowed based on the sonobuoy search. The anti-submarine warfare target used for this exercise may be a MK-39 Expendable Mobile Anti-submarine Warfare Training Target, a MK-30 target, or a live submarine. This exercise may involve a single aircraft, or occur during a coordinated larger exercise involving multiple aircraft and ships, including a major range event. Unmanned aerial systems, such as the MQ-8 Fire Scout, may also be used. The exercise torpedo is recovered by a special recovery helicopter or small craft. The preferred range for this exercise is an instrumented underwater range, but it may be conducted anywhere within the Study Area depending on training requirements and available assets.		
Typical Components	**Platforms:** Rotary-wing aircraft, unmanned aerial system - rotary wing, surface vessels, small boats **Targets:** Sub-surface targets **Systems being Trained/Tested:** Mid-frequency sonar, torpedoes

A.1.4.2 Torpedo Exercise – Maritime Patrol Aircraft

Anti-Submarine Warfare			
Anti-Submarine Warfare Torpedo Exercise – Maritime Patrol Aircraft (TORPEX)			
Short Description	Maritime patrol aircraft crews search for, track, and detect submarines. Recoverable air launched torpedoes are employed against submarine targets.	**Typical Duration**	2–8 hours
Long Description	Fixed-wing maritime patrol aircraft employ sonobuoys to search for, detect, classify, localize, and track a simulated threat submarine with the goal of determining a firing solution that could be used to launch a torpedo and destroy the submarine. The exercise may be conducted on a portable underwater tracking range. Sonobuoys (both passive and active) are typically employed by a maritime patrol aircraft operating at altitudes below 3,000 feet. However, sonobuoys may be released at higher altitudes. Sonobuoys are deployed in specific patterns based on the expected threat submarine and specific water conditions. Depending on these two factors, these patterns will cover many different size areas. For certain sonobuoys, tactical parameters of use may be classified. The anti-submarine warfare target used for this exercise may be a MK-39 Expendable Mobile Anti-Submarine Warfare Training Target, a MK-30 target, or a live submarine. This exercise may involve a single aircraft, or be undertaken in the context of a coordinated larger exercise involving multiple aircraft and vessels, including a major range event. The exercise torpedo is recovered by helicopter or small craft. The preferred range for this exercise is an instrumented underwater range, but it may be conducted anywhere within the Study Area depending on training requirements and available assets.

A.1.5 ELECTRONIC WARFARE

Electronic warfare is the mission area of naval warfare that aims to control use of the electromagnetic spectrum and to deny its use by an adversary. Typical electronic warfare activities include threat avoidance training, signals analysis for intelligence purposes, and use of airborne and surface electronic jamming devices to defeat tracking systems.

A.1.5.1 Counter Targeting Chaff Exercise – Aircraft

<table>
<tr><th colspan="6">Electronic Warfare</th></tr>
<tr><th colspan="6">Counter Targeting Chaff Exercise – Aircraft</th></tr>
<tr><td>Short Description</td><td colspan="3">Fixed-wing aircraft and helicopter aircrews deploy chaff to disrupt threat targeting and missile guidance radars.</td><td>Typical Duration</td><td>1–2 hours</td></tr>
<tr><td>Long Description</td><td colspan="5">Fixed-wing aircraft and helicopter aircrews deploy chaff to disrupt threat targeting and missile guidance radars.

Fixed-wing aircraft and helicopter aircrews detect electronic targeting signals from threat radars or missiles, dispense chaff, and immediately maneuver to defeat the threat. The chaff cloud deceives the inbound missile and the aircraft clears away from the threat.

Chaff is a radar reflector material made of thin, narrow, metallic strips cut in various lengths to elicit frequency responses, which deceive enemy radars. Chaff is employed to create a target that will lure enemy radar and weapons system away from the actual friendly platform.</td></tr>

<tr><th colspan="6">Counter Targeting Chaff Exercise – Ship</th></tr>
<tr><td>Short Description</td><td colspan="3">Surface ship crews deploy chaff to disrupt threat targeting and missile guidance radars.</td><td>Typical Duration
1–2 hours</td><td></td></tr>
<tr><td>Long Description</td><td colspan="5">Surface ship crews deploy chaff to disrupt threat targeting and missile guidance radars to defend against an attack.

Surface ship crews detect electronic targeting signals from threat radars or missiles, dispense chaff, and immediately maneuver to defeat the threat. The chaff cloud deceives the inbound missile and the vessel clears away from the threat. The typical event duration is approximately one and one-half hours.

Chaff is a radar reflector material made of thin, narrow, metallic strips cut in various lengths to elicit frequency responses, which deceive enemy radars. Chaff is employed to create a target that will lure enemy radar and weapons system away from the actual friendly platform. Ships may also train with advanced countermeasure systems, such as the MK 53 Decoy Launching System (Nulka).</td></tr>

<table>
<tr><th colspan="6">Electronic Warfare</th></tr>
<tr><th colspan="6">Counter Targeting Flare Exercise - Aircraft</th></tr>
<tr><td>Short Description</td><td colspan="3">Fixed-wing aircraft and helicopter aircrews deploy flares to disrupt threat infrared missile guidance systems.</td><td>Typical Duration</td><td>1–2 hours</td></tr>
<tr><td>Long Description</td><td colspan="5">Fixed-wing aircraft and helicopter aircrews deploy flares to disrupt threat infrared missile guidance systems. Range personnel acting as opposition forces may use pyrotechnics to simulate missile launch.

Aircraft detect electronic targeting signals from threat radars or missiles, or a threat missile plume, when launched and dispense flares and immediately maneuver to defeat the threat. This exercise trains aircraft personnel in the use of defensive flares designed to confuse infrared sensors or infrared homing missiles, thereby causing the sensor or missile to lock onto the flares instead of the real aircraft. Typically an aircraft will expend five flares in an exercise while operating above 3,000 feet. Flare exercises are often conducted with chaff exercises, rather than as a stand-alone exercise.</td></tr>
<tr><td>Typical Components</td><td colspan="5">Platforms: Fixed-wing aircraft, rotary-wing aircraft

Expeditionary Warfare	
Personnel Insertion/Extraction	
Assumptions Used for Analysis	During the conduct of insertion/extraction activities personnel may exit the watercraft in the surf zone and divers and combat swimmers will stand in the surf zone and walk onto the beach.

A.1.7 MINE WARFARE

Mine warfare is the naval warfare area involving the detection, avoidance, and neutralization of mines to protect Navy ships and submarines, and offensive mine laying in naval operations. A naval mine is a self-contained explosive device placed in water to destroy ships or submarines. Naval mines are deposited and left in place until triggered by the approach of an enemy ship, or are destroyed or removed. Naval mines can be laid by purpose-built minelayers, other ships, submarines, or airplanes. Mine warfare training includes mine countermeasure exercises, mine laying, and recovery exercises. Recovery of mine shapes and targets can include raising and towing the training aides to shore.

A.1.7.5 Mine Countermeasure – Towed Mine Neutralization

Mine Warfare			
Mine Countermeasures – Towed Mine Neutralization			
Short Description	Helicopter aircrews, manned and unmanned vehicles tow systems through the water which are designed to disable or trigger mines.	**Typical Duration**	Up to 12 hours
Long Description	Helicopter, vehicle operators and unmanned vehicles use towed devices to trigger mines that are designed to detonate when they detect ships/submarines by engine/propeller sounds or magnetic (steel construction) signature. Towed devices can also employ cable cutters to detach floating moored mines. Training will be conducted either with non-explosive training mine shapes or without any mine shapes. A high degree of pilot skill is required in deploying devices, safely towing them at relatively low speeds and altitudes, and then recovering devices. Devices used may include the following: Organic Airborne and Surface Influence Sweep (OASIS). The Organic Airborne and Surface Influence Sweep is a towed device that imitates the magnetic and acoustic signatures of naval ships and submarines. MK 105 sled: the MK 105 sled, similar to the Organic Airborne and Surface Influence Sweep, creates a magnetic field used to trigger mines. The MK 105 sled can also be used in conjunction with the MK 103 cable cutter system and the MK 104 acoustic countermeasure. AN/SPU-1/W "Magnetic Orange Pipe": As the name implies, the AN/SPU-1/W is a magnetic pipe that is used to trigger magnetically influenced mines.		
Typical Components	**Platforms:** Mine warfare ship, rotary-wing aircraft, unmanned surface vehicle **Targets:** Mine Shapes **Systems being Trained/Tested:** Electromagnetic devices		
Standard Operating Procedures *(Section 2.3.3)*	Aircraft safety Towed in-water device safety Vessel safety Unmanned surface vehicle safety Pierside testing safety Target deployment and retrieval safety	**Typical Locations**

Mine Warfare			
Mine Countermeasures – Towed Mine Neutralization			
Military Expended Material	**Ingestible Material:** None **Non-Ingestible Material:** None	**Military Recoverable Material**	Mine shape (non-explosive)
Sonar and Other Transducer Bins	None		
Explosive Bins	None		
Procedural Mitigation Measures	**Physical Disturbance and Strike Stressors:** *(Section 5.3.4)* Vessel movement Towed in-water devices		
Assumptions Used for Analysis	Mechanical sweeping (cable cutting), acoustic and magnetic influence sweeping devices are towed from helicopters, surface vessels, and unmanned vehicles. Cable cutters utilize an insignificant charge (similar to a shotgun shell). Acoustic sweeps generate ship type noise via a mechanical system. Towing systems though minefields (or without mines, to train to deploy, tow, and recover) may involve instrumented mines. Mine shapes would be recovered.		

A.1.7.6 Mine Countermeasure – Towed Mine Detection

<table>
<tr><th colspan="6">Mine Warfare</th></tr>
<tr><th colspan="6">Mine Countermeasures – Towed Mine Detection</th></tr>
<tr><td>Short Description</td><td colspan="3">Helicopter aircrews, manned and unmanned vehicles detect mines using towed or laser mine detection systems.</td><td>Typical Duration</td><td>Typically 1.5 hours up to 4 hours</td></tr>
<tr><td>Long Description</td><td colspan="5">Helicopter aircrews, manned and unmanned vehicles use towed and airborne devices to detect, locate, and classify potential mines. Towed devices employ active acoustic sources, such as high-frequency and side scanning sonar. These devices are similar in function to systems used to map the seafloor or locate submerged structures/items. Airborne devices utilize laser systems to locate mines located below the surface.

Devices used include the ANAQS-20/A, towed mine-hunting sonar used to detect and classify bottom and floating/moored mines in deep and shallow water, and the Airborne Laser Mine Detection System, developed to detect and classify floating and near-surface, moored mines.</td></tr>

Mine Warfare	
Mine Countermeasures – Towed Mine Detection	
Procedural Mitigation Measures	**Physical Disturbance and Strike Stressors:** *(Section 5.3.4)* Towed in-water devices Vessel movement
Assumptions Used for Analysis	Sonar mine detection systems towed from helicopters and surface vessels. Airborne laser systems used to detect mine shapes. Laser systems are similar to commercial Light Detection And Ranging systems. The in-air low energy laser stressor was used in analysis of potential impacts on human resources. Mine shapes may be deployed via ship and will be recovered.

A.1.7.7 Mine Countermeasure Exercise – Towed Sonar

Mine Warfare				
Mine Countermeasure Exercise – Towed Sonar				
Short Description	Surface ship crews detect and avoid mines while navigating restricted areas or channels using towed active sonar systems.	**Typical Duration**	1–4 hours	
Long Description	Surface vessel crews detect and avoid mines or other underwater hazardous objects while navigating restricted areas or channels using active sonar. Littoral Combat Ship utilizes unmanned surface vehicles and remotely operated vehicles to tow mine detection (hunting) equipment. Systems will operate from shallow zone greater than 40 feet to deep water. Events could be embedded in major training exercises.			
Typical Components	**Platforms:** Surface combatant, unmanned aerial vehicles, unmanned surface vehicles **Targets:** Mine shapes **Systems being Trained/Tested:** High frequency sonar			
Standard Operating Procedures *(Section 2.3.3)*	Unmanned aerial, surface, and subsurface vehicle safety Vessel safety Laser Procedures Target deployment and retrieval safety	**Typical Locations**		
		Range Complexes/Testing Ranges: Mariana Islands Training and Testing Study Area	**Bays/Estuaries/Pierside:** Apra Harbor	
Stressors to Biological Resources	**Acoustic:** Sonar and other transducers Vessel noise **Explosive:** None	**Physical Disturbance and Strike:** Aircraft and aerial targets Vessel and in-water devices Seafloor devices **Ingestion:** None	**Energy:** In-air electromagnetic devices In-water electromagnetic devices **Entanglement:** None	
Stressors to Physical Resources	**Air Quality:** Criteria air pollutants	**Sediments and Water Quality:** Explosives		
Stressors to Human Resources	**Cultural Resources:** Physical disturbance and strike	**Socioeconomic Resources:** Accessibility Airborne acoustics Physical disturbance and strike	**Public Health and Safety:** In-water energy Physical interactions	
Military Expended Material	**Ingestible Material:** None **Non-Ingestible Material:** None	**Military Recoverable Material**	Mine shapes (non-explosive)	
Sonar and Other Transducer Bins	**High Frequency:** HF4			
Explosive Bins	None			
Procedural Mitigation Measures	**Acoustic Stressors:** *(Section 5.3.2)* Active sonar	**Physical Disturbance and Strike Stressors:** *(Section 5.3.4)* Vessel movement Towed-in water devices		

Mine Warfare	
Mine Countermeasure Exercise – Towed Sonar	
Assumptions Used for Analysis	No explosives used. Constraints: Assume system will be operated in areas free of obstructions, and will be towed well above the seafloor. Towed system will be operated in a manner to avoid entanglement and damage. Events will take place in water depths 40 feet and greater. Existing placed mine shapes to be used. Potential for temporary placement of mine shapes.

A.1.7.8 Mine Laying

A.1.9 SURFACE WARFARE TRAINING

Surface warfare is a type of naval warfare in which aircraft, surface ships, and submarines employ weapons and sensors in operations directed against enemy surface ships or small boats. Aircraft-to-surface warfare is conducted by long-range attacks using air-launched cruise missiles, precision guided munitions, or aircraft guns. Surface warfare also is conducted by warships employing torpedoes, naval guns, and surface-to-surface missiles. Submarines attack surface ships using torpedoes or submarine-launched, anti-ship cruise missiles. Training in surface warfare includes surface-to-surface gunnery and missile exercises, air-to-surface gunnery and missile exercises, and submarine missile or torpedo launch events. Gunnery and missile training generally involves expenditure of ordnance against a towed target. A sinking exercise is a specialized training event that provides an opportunity for ship, submarine, and aircraft crews to use multiple weapons systems to deliver high-explosive ordnance on a deactivated vessel, which is deliberately sunk.

Surface warfare also encompasses maritime security, that is, the interception of a suspect surface ship by a Navy ship for the purpose of boarding-party inspection or the seizure of the suspect ship. Training in these tasks is conducted in visit, board, search and seizure exercises.

A.1.9.1 Bombing Exercise Air-to-Surface

<table>
<tr><td colspan="5">Surface Warfare</td></tr>
<tr><td colspan="5">Bombing Exercise Air-to-Surface</td></tr>
<tr><td>Short Description</td><td colspan="2">Fixed-wing aircrews deliver bombs against surface targets.</td><td>Typical Duration
1 hour</td><td></td></tr>
<tr><td>Long Description</td><td colspan="4">Fixed-wing aircraft conduct bombing exercises against stationary floating targets (e.g., MK-58 smoke buoy), towed targets, or maneuvering targets. An aircraft clears the area, deploys a smoke buoy, and then delivers high-explosive or non-explosive practice munitions bomb(s) on the target. A range boat may be used to deploy towed or maneuvering targets for an aircraft to attack.

Exercises for strike fighters typically involve a flight of two aircraft delivering unguided or guided munitions that may be either high-explosive or non-explosive. The following munitions may be employed by strike fighter aircraft in the course of bombing exercise: Unguided munitions include non-explosive subscale bombs (MK-76 and BDU-45), explosive and non-explosive general purpose bombs (MK-80 series), MK-20 cluster bomb (explosive, non-explosive). Precision-guided munitions include laser-guided bombs (explosive, non-explosive), laser-guided training rounds (non-explosive), Joint Direct Attack Munition (explosive, non-explosive).</td></tr>
<tr><td>Typical Components</td><td colspan="4">Platforms: Fixed-wing aircraft, support craft

Surface Warfare				
Bombing Exercise Air-to-Surface				
Sonar and Other Transducer Bins	None			
Explosive Bins	E9	E10	E12	
Procedural Mitigation Measures	**Explosive Stressors:** *(Section 5.3.3)* Explosive bombs			**Physical Disturbance and Strike Stressors:** *(Section 5.3.4)* Vessel movement Non-explosive bombs and mine shapes
Assumptions Used for Analysis	Explosive bombs are assumed to explode just below the surface. This activity would occur at least 12 NM from land (FDM excepted).			

A.1.9.2 Gunnery Exercise Air-to-Surface Medium-Caliber

Surface Warfare			
Gunnery Exercise Air-to-Surface Medium-Caliber			
Short Description	Fixed-wing and helicopter aircrews fire medium-caliber guns at surface targets.	**Typical Duration**	1 hour
Long Description	Fighter and helicopter aircrew, engage surface targets with medium-caliber guns. Targets simulate enemy ships, boats, swimmers, and floating/near- surface mines. Fighter aircraft descend on a target firing high-explosive or non-explosive practice munitions medium-caliber projectiles. Helicopters will fly a racetrack pattern around an at-sea target. Aircrew will engage the target with medium-caliber weapons. Targets range from a smoke float, or an empty steel drum, to high-speed remote-controlled boats and jet-skis.		
Typical Components	**Platforms:** Fixed-wing aircraft, rotary-wing aircraft, support vessels **Targets:** Surface targets **Systems being Trained/Tested:** Medium-caliber gun systems		
Standard Operating Procedures *(Section 2.3.3)*	Aircraft safety Weapons firing safety Target deployment and retrieval safety	**Typical Locations** **Range Complexes/Testing Ranges:** Mariana Islands Training and Testing Study Area, Primary areas: Special Use Airspace	**Bays/Estuaries/Pierside:** None

Assumptions Used for Analysis	One target used per event. Expendable smoke float (50 percent), stationary target (45 percent), or remote-controlled target (5 percent). This activity occurs greater than 12 NM from land.	

A.1.9.4 Gunnery Exercise Surface-to-Surface Boat Medium-Caliber

<table>
<tr><th colspan="6">Surface Warfare</th></tr>
<tr><th colspan="6">Gunnery Exercise Surface-to-Surface Boat Medium-Caliber</th></tr>
<tr><td>Short Description</td><td colspan="3">Small boat crews fire medium-caliber guns at surface targets.</td><td>Typical Duration</td><td>1 hour</td></tr>
<tr><td>Long Description</td><td colspan="5">Small boat crews fire medium-caliber guns at surface targets. Boat crews may use high or low speeds to approach and engage targets simulating other boats, floating mines, or nearshore land targets with medium-caliber (up to and including 40-millimeter [mm]) weapons. A commonly used target is an empty steel drum. This event also includes use of anti-swimmer grenades, which may be employed within harbors.

A number of different types of boats are used depending on the unit using the boat and their mission. Boats are most used to protect ships in harbors and high value units, such as: aircraft carriers, nuclear submarines, liquid natural gas tankers, etc., while entering and leaving ports, as well as to conduct riverine operations, and various naval special warfare operations. The boats used by these units include small unit river craft, combat rubber raiding craft, rigid-hull inflatable boats, patrol craft, and many other versions of these types of boats. These boats use inboard or outboard, diesel or gasoline engines with either propeller or water jet propulsion.</td></tr>

A.1.9.6 Gunnery Exercise Surface-to-Surface Ship Large-Caliber

<table>
<tr><td colspan="4">Surface Warfare</td></tr>
<tr><td colspan="4">Gunnery Exercise Surface-to-Surface Ship – Large-Caliber</td></tr>
<tr><td>Short Description</td><td colspan="2">Surface ship crews fire large-caliber guns at surface targets.</td><td>Typical Duration
Up to 3 hours</td></tr>
<tr><td>Long Description</td><td colspan="3">This exercise involves ships' gun crews engaging surface targets at sea with their main battery large-caliber (typically 57 millimeter [mm], 76 mm, and 5-inch) guns. Targets include the QST-35 seaborne powered target, high speed maneuverable surface target, or a specially configured remote-controlled water craft. Some targets are expended during the exercise and are not recovered.

The exercise proceeds with the target boat approaching from about 10 nautical miles distance. The target is tracked by radar and when within a predetermined range, it is engaged first with large-caliber "warning shots." As threats get closer all weapons may be used to disable the threat.

This exercise may involve a single firing ship, or be undertaken in the context of a coordinated larger exercise involving multiple ships, including a major training exercise.

Large-caliber guns will also be fired during weapon certification events and in conjunction with weapon maintenance.

During all events, either high-explosive or non-explosive rounds may be used. High-explosive rounds can either be fused for detonation on impact (with water surface or target), or for proximity to the target (in-air detonation).</td></tr>
<tr><td>Typical Components</td><td colspan="3">Platforms: Surface combatant

</table>

Surface Warfare	
Laser Targeting – At-Sea	
Assumptions Used for Analysis	Laser targeting for missile/rocket guidance will occur in areas where these events also occur. Use of lasers as force protection non-lethal deterrents will primarily occur proximate to Navy homeports.

A.1.9.9 Maritime Security Operations

<table>
<tr><th colspan="4">Surface Warfare</th></tr>
<tr><th colspan="4">Maritime Security Operations</th></tr>
<tr><td>Short Description</td><td colspan="2">Helicopter, surface ship, and small boat crews conduct a suite of maritime security operations at sea, to include visit, board, search and seizure, maritime interdiction operations, force protection, and anti-piracy operations.</td><td>Typical Duration
Up to 3 hours</td></tr>
<tr><td>Long Description</td><td colspan="3">Helicopter and surface ship crews conduct a suite of maritime security operations (e.g., visit, board, search and seizure, maritime interdiction operations, force protection, and anti-piracy operations). These activities involve training of boarding parties delivered by helicopters and surface ships to surface vessels for the purpose of simulating vessel search and seizure operations. Various training scenarios are employed and may include small arms with non-explosive blanks, explosive Anti-Swimmer Grenades, and surveillance or reconnaissance unmanned surface and aerial vehicles. The entire exercise may last 2–3 hours.

Vessel Visit, Board, Search, and Seizure: Military personnel from ships and aircraft board suspect vessels, potentially under hostile conditions.

Maritime Interdiction Operations: Ships and aircraft train in pursuing, intercepting, and ultimately detaining suspect vessels.

Maritime Infrastructure Protection and Harbor Defense: Naval personnel train to defend oil platforms, similar at-sea structures, harbors, piers, and other infrastructure.

Warning Shot/Disabling Fire: Naval personnel train in the use of weapons to force fleeing or threatening small boats (typically operating at high speeds) to come to a stop.

Ship Force Protection: Ship crews train in tracking multiple approaching, circling small craft, assessing threat potential, and communicating amongst crewmates and other vessels to ensure ships are protected against attack.

Anti-Piracy Training: Naval and U.S. Coast Guard personnel train in deterring and interrupting piracy activity. Training includes large vessels (pirate “mother ships”), and multiple small, maneuverable, and fast craft.</td></tr>
<tr><td>Typical Components</td><td colspan="3">Platforms: Amphibious warfare ship, rotary-wing aircraft, small boat, surface combatant, unmanned aerial vehicle, unmanned surface vehicle

Vessel movement</td><td colspan="2">Explosive Stressors: (Section 5.3.3)
Maritime security operations – Anti-swimmer grenades</td></tr>
<tr><td>Assumptions Used for Analysis</td><td colspan="4">Maritime Security Operations is a broad term used to describe activities intended train naval forces in the skills necessary to protect naval vessels from small boat attack, counter piracy and drug operations (maritime interdiction operations and visit, board, search, and seizure), and protect key infrastructure (e.g., oil platforms). Maritime security operations need to remain broad as naval forces need to be able to tailor training events to respond to emergent threats. Maritime Security Operations events typically do not involve live fire of weapons; however, the use of various non-lethal deterrents is likely. All maritime security operations events involve vessel movement, sometimes at high rates of speed (naval vessels maneuvering to overtake suspect vessel or small boats (targets) closing in and maneuvering around naval vessels), and some event involve helicopters and boarding parties. Maritime security operations training events are typically conducted proximate to naval homeports including during times of transit in and out of port, as well as during major training exercises. These events may occur in littorals throughout the Study Area..</td></tr>

<table>
<tr><th colspan="5">Surface Warfare</th></tr>
<tr><th colspan="5">Missile Exercise Surface-to-Surface</th></tr>
<tr><td>Short Description</td><td colspan="3">Surface ship crews defend against surface threats (ships or small boats) and engage them with missiles.</td><td>Typical Duration
2–5 hours</td></tr>
<tr><td>Long Description</td><td colspan="4">Surface ships launch missiles at surface maritime targets with the goal of destroying or disabling enemy ships or boats.

After detecting and confirming a surface threat, the ship will fire a precision guided surface missile.

Events with destroyers and cruisers will involve long range (over the horizon) Harpoon (or similar) surface missiles. While past Harpoon events occurred during sinking exercises, the requirement exists for non-sinking exercise events to certify ship crews. If a sinking exercise target is unavailable, a towed sled would likely be used.

Events with littoral combat and patrol combatant ships will involve shorter range surface missiles, such as Hellfire and Griffin. Events with littoral combat and patrol combatant ships would be to certify ship's crew to defend against "close-in" (less than 10 miles) surface threats.

These exercises are live fire, meaning that a missile is fired down range. Surface missiles could be equipped with either high-explosive or non-explosive warheads.</td></tr>
<tr><td>Typical Components</td><td colspan="4">Platforms: Surface combatant

Surface Warfare			
Missile Exercise Surface-to-Surface			
Military Expended Material	**Ingestible Material:** Missile (explosive) fragments, target fragments **Non-Ingestible Material:** None	**Military Recoverable Material**	Surface target (mobile and stationary)
Sonar and Other Transducer Bins	None		
Explosive Bins	E6 E10		
Procedural Mitigation Measures	**Acoustic Stressors** *(Section 5.3.2)* Weapons firing noise **Physical Disturbance and Strike Stressors** *(Section 5.3.4)* Vessel movement **Explosive Stressors** (*Section 5.3.3*) Explosive missiles and rockets		
Assumptions Used for Analysis	Assume one missile and one target used per event. While missile could explode above water's surface after contacting target, analysis assumes all warheads explode at or just below surface. Targets are usually recovered but could be lost due to damage. This activity would occur greater than 50 NM from land (FDM excepted).		

A.1.9.13 Sinking Exercise

<table>
<tr><th colspan="4">Surface Warfare</th></tr>
<tr><th colspan="4">Sinking Exercise</th></tr>
<tr><td>Short Description</td><td colspan="2">Aircraft, ship, and submarine crews deliberately sink a seaborne target, usually a decommissioned ship made environmentally safe for sinking according to U.S. Environmental Protection Agency standards, with a variety of ordnance.</td><td>Typical Duration
4–8 hours, possibly over 1–2 days</td></tr>
<tr><td>Long Description</td><td colspan="3">Ship personnel and aircrew deliver high-explosive ordnance on a seaborne target, (large deactivated vessel), which is deliberately sunk using multiple weapon systems. A sinking exercise is typically conducted by aircraft, surface vessels, and submarines to train in live ordnance delivery on a full-size ship target.

The target is typically a decommissioned ship made environmentally safe for sinking according to U.S. Environmental Protection Agency standards. The location is greater than 50 nautical miles from shore and in water depths greater than 6,000 feet (ft.).

Ship, aircraft, and submarine crews attack with coordinated tactics and deliver a variety of inert and high-explosive ordnance. Typically, the exercise lasts for 4–8 hours and possibly over 1–2 days; however, it is unpredictable and ultimately ends when the target ship sinks.</td></tr>
<tr><td>Typical Components</td><td colspan="3">Platforms: Fixed-wing aircraft, submarines, support craft, surface combatant

Sinking Exercises</td></tr>
<tr><td>Assumptions Used for Analysis</td><td colspan="5">Events occur greater than 50 nautical miles from shore and in water depths greater than 6,000 ft. during daylight hours only.
The participants and assets typically include:
• 1 full-size target ship hulk
• 1–5 CG, DDG, or LCS ships
• 1-10 Fixed-wing aircraft (e.g., F/A-18, or maritime patrol aircraft)
• 1 or 2 MH-60 helicopters
• 1 E-2 aircraft for Command and Control
• 1 submarine
• 1–3 range clearance aircraft
For purposes of analysis, the below represents the types of munitions that might be employed. Actual SINKEX ordnance expenditures will vary.
• 1–2 Harpoon surface-to-surface or air-to-surface missiles
• 2–4 Maverick or Hellfire air-to-surface missiles
• 2–12 MK-80 series general purpose bombs
• 200 rounds large-caliber projectiles
• 1–2 MK-48 heavyweight submarine-launched torpedo
• Assume 2 guidance wires expended per event
Acoustic effects modeling assumed only a percentage of munitions missed target and exploded in water. Precision guided munitions are assumed to impact target well above waterline and are not modeled (or reported) as in water explosions.</td></tr>
</table>

A.1.10 OTHER TRAINING EXERCISES

A.1.10.1 Direct Action (Tactical Air Control Party)

Other Training Exercises			
Direct Action (Tactical Air Control Party)			
Short Description	Military personnel train for controlling of combat support aircraft; providing airspace de-confliction and terminal control for Close Air Support.	**Typical Duration**	Multiple days
Long Description	Tactical Air Control personnel, once at Farallon de Medinilla, participate in tactical air control training in conjunction with an Air-to-Ground bombing or missile exercise. They may also employ small arms, grenades, mortars, and crew served weapons in direct action against targets on the island.		
Typical Components	**Platforms:** Fixed-wing aircraft, rotary-wing aircraft, small boats **Targets:** None **Systems being Trained/Tested:** Small-caliber rounds, explosive grenades and mortars		
Standard Operating Procedures *(Section 2.3.3)*	Aircraft safety Vessel safety Laser procedures Target Deployment and Retrieval Safety Farallon de Medinilla Access Restrictions	**Typical Locations** **Range Complexes/Testing Ranges:** Farallon de Medinilla	**Bays/Estuaries/Pierside:** None

A.2 TESTING ACTIVITIES

A.2.1 NAVAL AIR SYSTEMS COMMAND TESTING ACTIVITIES

Naval Air Systems Command activities will generally fall under Fleet primary mission areas, such as the testing of airborne mine warfare and anti-submarine warfare weapons and systems. Naval Air Systems Command activities include, but are not limited to, the testing of new aircraft platforms (e.g., the P-8 maritime patrol aircraft), weapons, and systems (e.g., newly developed sonobuoys) that will ultimately be integrated into Fleet training activities. In addition to testing new platforms, weapons, and systems, Naval Air Systems Command also conducts lot acceptance testing of sonobuoys and follow-on testing and evaluation of updated systems in support of Fleet operational units. In general, the potential environmental effects from most Naval Air Systems Command testing events are similar to the associated Fleet training events.

While many of these systems tested by Naval Air Systems Command will ultimately be used by the Fleet, testing activities involving the same or similar systems may be conducted in different locations and manners than when conducted by the Fleet. Because of these differences, the results of the analysis for testing activities may differ from the results for training activities.

A.2.1.1 Anti-Submarine Warfare

A.2.1.1.1 Anti-Submarine Warfare Torpedo Test

<table>
<tr><th colspan="4">Anti-Submarine Warfare</th></tr>
<tr><th colspan="4">Anti-Submarine Warfare Torpedo Test</th></tr>
<tr><td>Short Description</td><td colspan="2">This event is similar to the training event torpedo exercise. Test evaluates anti-submarine warfare systems onboard rotary-wing and fixed-wing aircraft and the ability to search for, detect, classify, localize, track, and attack a submarine or similar target.</td><td>Typical Duration
2–6 flight hours per event</td></tr>
<tr><td>Long Description</td><td colspan="3">Similar to a torpedo exercise, an anti-submarine warfare (ASW) torpedo test evaluates anti-submarine warfare systems onboard rotary-wing (e.g., MH-60R helicopter) and fixed-wing (marine patrol aircraft P-8, P-3) aircraft and the ability to search for, detect, classify, localize, track, and attack a submarine or similar target (e.g., MK-39 expendable mobile ASW training target [EMATT], or MK-30). The focus of the anti-submarine warfare torpedo test is the operation of non-explosive torpedoes (e.g., MK-46 or MK-54), but other anti-submarine warfare systems are often used during the test. MK-39 (EMATT) or MK-30 targets simulate a submarine threat and are deployed at varying depths and speeds. If available, tests may be conducted using an actual submarine as the target. This activity can be conducted in shallow or deep waters and aircraft can originate from a land base or from a surface ship. The torpedo test culminates with the release of an exercise torpedo against the target and is intended to evaluate the targeting, release, and tracking process of deploying torpedoes from aircraft. All exercise torpedoes used in testing are either running or non- running and are non-explosive. Eighty-five percent of torpedoes are recovered. A parachute assembly used for aircraft-launched torpedoes is jettisoned and sinks. Ballast (typically lead weights) may be released from the torpedoes to allow for recovery, and sink to the bottom.</td></tr>
<tr><td>Typical Components</td><td colspan="3">Platforms: Fixed-wing aircraft, rotary-wing aircraft, range support craft

A.2.1.3 Surface Warfare

Surface warfare is a type of naval warfare in which aircraft, surface ships, and submarines employ weapons, sensors, and operations directed against enemy surface vessels. Naval Air Systems Command surface warfare tests include air-to-surface missile, gunnery, and bombing tests, rocket tests, laser targeting tests, and high-energy laser weapons tests.

A sinking exercise is a specialized Fleet training event that provides an opportunity for Naval Air Systems Command aircrew along with ship and submarine crews to deliver explosive ordnance on a deactivated vessel that has been cleaned and environmentally remediated. The vessel is deliberately sunk using multiple weapons systems. A Naval Air Systems Command testing event may take place in conjunction with a sinking exercise to test aircraft or aircraft systems in the delivery of explosive ordnance on a surface target.

Radar and Other System Testing	
Sonar and Other Transducer Bins	None
Explosive Bins	None
Procedural Mitigation Measures	**Physical Disturbance and Strike Stressors:** *(Section 5.3.4)* Vessel movement
Assumptions Used for Analysis	High-energy lasers will not be tested pierside. Any sources used during this activity would be *de minimis* and not quantitatively analyzed and therefore are not included under munitions.

A.2.2.3 Mine Warfare

A.2.2.3.1 Mine Countermeasure and Neutralization Testing

<table>
<tr><th colspan="5">Mine Warfare</th></tr>
<tr><th colspan="5">Mine Countermeasure and Neutralization Testing</th></tr>
<tr><td>Short Description</td><td colspan="2">Air, surface, and subsurface vessels neutralize threat mines and mine-like objects.</td><td colspan="2">Typical Duration
1–10 days, with intermittent use of countermeasure/neutralization systems during this period</td></tr>
<tr><td>Long Description</td><td colspan="4">Mine countermeasure-neutralization and mine system testing is required to ensure systems can effectively neutralize threat (live or inert) mines that will otherwise restrict passage through an area and to ensure U.S. Navy mines remain effective against enemy ships. These systems may be deployed with a variety of ships, aircraft, submarines, or unmanned autonomous vehicles and operate in water depths up to 6,000 feet. Mines are neutralized by cutting mooring cables of buoyant mines, producing acoustic energy that fires acoustic-influence mines, employing radar or laser fields, producing electrical energy to replicate the magnetic signatures of surface ships in order to detonate threat mines, detonation of mines using remotely-operated vehicles, and using explosive charges to destroy threat mines.</td></tr>
<tr><td>Typical Components</td><td colspan="4">Platforms: Amphibious warfare ship, mine warfare ship, unmanned aerial system – rotary-wing, rotary-wing aircraft, surface combatant, unmanned underwater vehicle
Targets: Mine shapes
Systems being Trained/Tested: Electromagnetic devices, high-frequency sonar, radar, low energy lasers</td></tr>

</table>

Other Testing Activities	
Simulant Testing	
Assumptions Used for Analysis	All chemical simulants have low toxicity to humans and the environment. Examples of chemical simulants include glacial acetic acid and triethyl phosphate. All biological simulants are considered to be Biosafety Level 1 organisms. Examples of biological simulants are spore-forming bacteria, non-spore-forming bacteria, the protein ovalbumin, MS2 bacteriophages, and the fungus *Aspergillus niger*.

A.2.3 Office of Naval Research Testing Activities

A.2.3.1 Acoustic and Oceanographic Research

Acoustic and Oceanographic Science and Technology				
Acoustic and Oceanographic Research				
Short Description	Research of oceanographic processes using active transmissions, typically high-frequency (38 kHz and above) oceanographic measurement devices, deployed from ships, unmanned underwater vehicles and on moored platform	**Typical Duration**	1–2 weeks	
Long Description	ONR performs research on oceanographic processes in U.S. territorial waters and international waters using passive measurement devices and active acoustic systems such as acoustic Doppler current profilers and echosounders. Measurement systems may be deployed by ship, unmanned underwater vehicle, or on standard oceanographic moorings. Moorings may be left in place for more than 1 year.			
Typical Components	**Platforms:** Research vessels, unmanned vehicles, oceanographic moorings **Targets:** None **Systems being Trained/Tested:** None			
Standard Operating Procedures *(Section 2.3.3)*	Vessel safety Unmanned aerial and underwater vehicle procedures	**Typical Locations**		
		Range Complexes/Testing Ranges: Mariana Islands Training and Testing Study Area	**Inland Waters/Pierside:** None	
Stressors to Biological Resources	**Acoustic:** Vessel noise **Explosive:** None	**Physical Disturbance and Strike:** Vessel and in-water devices Seafloor devices **Ingestion:** None	**Energy:** None **Entanglement:** None	
Stressors to Physical Resources	**Air Quality:** Criteria air pollutants	**Sediments and Water Quality:** None		
Stressors to Human Resources	**Cultural Resources:** None	**Socioeconomic Resources:** Accessibility Airborne acoustics Physical disturbance and strike	**Public Health and Safety:** In-water energy In-air energy Physical interactions	
Military Expended Material	**Ingestible Material:** None **Non-Ingestible Material:** None	**Military Recoverable Material**	None	
Sonar and Other Transducer Bins	None			
Explosive Bins	None			
Procedural Mitigation Measures	**Physical Disturbance and Strike Stressors:** *(Section 5.3.4)* Vessel movement			

Acoustic and Oceanographic Science and Technology	
Acoustic and Oceanographic Research	
Assumptions Used for Analysis	Approximately 12 non-recoverable bottom moorings may be used. Any sonar transducers used would be *de minimis*.

DEPARTMENT OF DEFENSE

Department of the Navy

Meeting of the Board of Visitors of Marine Corps University

AGENCY: Department of the Navy, DOD.
ACTION: Notice of open meeting.

SUMMARY: The Board of Visitors of the Marine Corps University (BOV MCU) will meet to review, develop and provide recommendations on all aspects of the academic and administrative policies of the University; examine all aspects of professional military education operations; and provide such oversight and advice, as is necessary, to facilitate high educational standards and cost effective operations. The Board will be focusing primarily on the internal procedures of Marine Corps University. All sessions of the meeting will be open to the public.

DATES: The meeting will be held on Thursday, September 14, 2017, from 9:00 a.m. to 4:30 p.m. and Friday, September 15, 2017, from 8:00 a.m. to 2:30 p.m. Eastern Time Zone.

ADDRESSES: The meeting will be held at Marine Corps University in Quantico, Virginia. The address is: 2076 South St., Quantico, VA.

FOR FURTHER INFORMATION CONTACT: Dr. Kim Florich, Director of Faculty Development and Outreach, Marine Corps University Board of Visitors, 2076 South Street, Quantico, Virginia 22134, telephone number 703–432–4682.

Dated: July 24, 2017.

A.M. Nichols,
Lieutenant Commander, Judge Advocate General's Corps, U.S. Navy, Federal Register Liaison Officer.

BILLING CODE 3810–FF–P

DEPARTMENT OF DEFENSE

Department of the Navy

Notice of Intent To Prepare a Supplemental Environmental Impact Statement/Overseas Environmental Impact Statement for Mariana Islands Training and Testing

AGENCY: Department of the Navy, DOD.
ACTION: Notice.

SUMMARY: Pursuant to the National Environmental Policy Act (NEPA) of 1969 and regulations implemented by the Council on Environmental Quality, the Department of the Navy (DoN) announces its intent to prepare a supplement to the 2015 Final Mariana Islands Training and Testing (MITT) Environmental Impact Statement/ Overseas Environmental Impact Statement (EIS/OEIS).

DATES: Public scoping meetings will not be held, but public comments will be accepted during the scoping period from August 1, 2017 to September 15, 2017.

ADDRESSES: The DoN invites scoping comments on the MITT Supplemental EIS/OEIS from all interested parties. Substantive comments may be provided by mail to the address below and through the project Web site at *http://mitt-eis.com/*. Comments must be postmarked or received by September 15, 2017, for consideration during the development of the Draft Supplemental EIS/OEIS.

FOR FURTHER INFORMATION CONTACT: Naval Facilities Engineering Command Pacific, Attention: MITT Supplemental EIS/OEIS Project Manager, 258 Makalapa Drive, Suite 100, Pearl Harbor, HI 96860–3134.

SUPPLEMENTARY INFORMATION: The Navy will assess the potential environmental impacts associated with ongoing and proposed military readiness activities conducted within the MITT EIS/OEIS Study Area (hereafter known as the "Study Area"). The Supplement to the 2015 Final EIS/OEIS is being prepared to support ongoing and future activities conducted at sea and on Farallon de Medinilla (FDM) within the Study Area beyond 2020. Military readiness activities include training and research, development, testing, and evaluation (hereafter known as "testing"). The Supplemental EIS/OEIS will include an analysis of training and testing activities using new information available after the release of the 2015 Final MITT EIS/ OEIS. New information includes an updated acoustic effects model, updated marine mammal density data, and other best available science. Proposed activities are generally consistent with those analyzed in the 2015 Final MITT EIS/OEIS and are representative of training and testing activities the DoN has been conducting in the Study Area for decades.

The Study Area remains unchanged since the 2015 Final MITT EIS/OEIS. The Study Area includes the existing Mariana Islands Range Complex (MIRC); areas on the high seas to the north and west of the MIRC; a transit corridor between the MIRC and the Hawaii Range Complex, starting at the International Date Line; and Apra Harbor and select DoN pierside and harbor locations. The Study Area includes only the in-water components of the range complex and FDM; land components associated with the range complex are not included in the Study Area.

As part of this process the DoN will seek the issuance of regulatory permits and authorizations under the Marine Mammal Protection Act and Endangered Species Act to support training and testing requirements within the Study Area, beyond 2020, thereby ensuring critical Department of Defense requirements are met.

Pursuant to 40 CFR 1501.6, the DoN will invite the National Marine Fisheries Service to be a cooperating agency in preparation of the Supplemental EIS/OEIS.

The DoN's lead action proponent is Commander, U.S. Pacific Fleet. Additional action proponents include Naval Sea Systems Command, Naval Air Systems Command, and the Office of Naval Research.

The DoN's Proposed Action is to conduct military training and testing activities within the Study Area. Activities include the use of active sonar and explosives while employing appropriate marine species protective mitigation measures. The Proposed Action does not alter the DoN's original purpose and need as presented in the 2015 MITT Final EIS/OEIS.

The purpose of the Proposed Action is to maintain a ready force, which is needed to ensure the military can accomplish its mission to maintain, train, and equip combat-ready naval forces capable of winning wars, deterring aggression, and maintaining freedom of the seas, consistent with Congressional direction in section 5062 of Title 10 of the U.S. Code. A Supplemental EIS/OEIS is considered the appropriate document, as there is recent scientific information including revised acoustic criteria to consider, in furtherance of NEPA, relevant to the environmental effects of the DoN's Proposed Action, and the analysis will support Marine Mammal Protection Act authorization requests.

Proposed training and testing activities are generally consistent to those analyzed in the 2015 MITT Final EIS/OEIS. The Supplemental EIS/OEIS will propose changes to the tempo and types of training and testing activities, accounting for the introduction of new technologies, the evolving nature of international events, advances in war fighting doctrine and procedures, and changes in the organization of vessels, aircraft, weapon systems, and military personnel. The MITT Supplemental EIS/OEIS will reflect the compilation of training and testing activities required to fulfill the DoN's military readiness requirements beyond 2020, and therefore includes the analysis of newly proposed activities and changes to previously analyzed activities.

In the Supplemental EIS/OEIS, the DoN will evaluate the potential environmental impacts of a No Action Alternative and action alternatives. Resources to be evaluated include, but are not limited to, marine mammals, sea turtles, essential fish habitat, and threatened and endangered species.

The scoping process is used to identify public concerns and local issues to be considered during the development of the Draft Supplemental EIS/OEIS. Federal agencies, local agencies, the public, and interested persons are encouraged to provide substantive comments to the DoN on environmental resources and issue areas of concern the commenter believes the DoN should consider.

Comments must be postmarked or received online by September 15, 2017, for consideration during the development of the Draft Supplemental EIS/OEIS. Comments can be mailed to: Naval Facilities Engineering Command Pacific, Attention: MITT Supplemental EIS/OEIS Project Manager, 258 Makalapa Drive, Suite 100, Pearl Harbor, HI, 96869–3134. Comments can be submitted online via the project Web site at *http://mitt-eis.com/*.

Dated: July 20, 2017.

A.M. Nichols,

Lieutenant Commander, Judge Advocate General's Corps, U.S. Navy, Federal Register Liaison Officer.

BILLING CODE 3810–FF–P

DEPARTMENT OF EDUCATION

Final Waiver and Extension of the Project Period for the Native American Career and Technical Education Program

[Catalog of Federal Domestic Assistance (CFDA) Number: 84.101A]

AGENCY: Office of Career, Technical, and Adult Education, Department of Education.

ACTION: Final waiver and extension of the project period.

SUMMARY: For the 24-month projects originally funded in fiscal year (FY) 2013 and extended for an additional 24-months in FY 2015 under the Native American Career and Technical Education Program (NACTEP), the Secretary: Waives the requirements in Education Department regulations that generally prohibit project extensions involving the obligation of additional Federal funds; and extends the project period for the current 30 NACTEP grantees for an additional 12 months under the existing program authority. This waiver and extension will allow the 30 current NACTEP grantees to seek FY 2017 continuation awards for the project period through FY 2018.

DATES: As of August 1, 2017, the waiver and extension of the project period are finalized.

FOR FURTHER INFORMATION CONTACT: Gwen Washington by telephone at (202) 245–7790 or by email at *gwen.washington@ed.gov*. You may also contact Linda Mayo by telephone at (202) 245–7792 or by email at *linda.mayo@ed.gov*. If you use a telecommunications device for the deaf (TDD) or a text telephone (TTY), call the Federal Relay Service, toll free, at 1–800–877–8339.

SUPPLEMENTARY INFORMATION: On April 26, 2017, we published a notice in the Federal Register (82 FR 19240) proposing to waive the requirements of 34 CFR 75.261(a) and (c)(2) that generally prohibit project period extensions involving the obligation of additional Federal funds. In that notice, the Secretary also proposed to extend the NACTEP project period for up to an additional 12 months. The proposed waiver and extension of project period would enable the Secretary to provide continuation awards to the current NACTEP grantees through FY 2018 under the existing program authority.

That notice contained background information and our reasons for proposing the waiver and extension of the project period. This notice makes the waiver and extension of the project period final. Any activities carried out during the period of a NACTEP continuation award must be consistent with, or a logical extension of, the scope, goals, and objectives of the grantee's application as approved in the FY 2013 NACTEP competition. The requirements applicable to continuation awards for this competition set forth in the 2013 notice inviting applications and the requirements in 34 CFR 75.253 will apply to any continuation awards sought by the current NACTEP grantees.

We will make decisions regarding the continuation awards based on grantee program narratives, budgets and budget narratives, program performance reports, and the requirements in 34 CFR 75.253. We will not announce a new competition or make new awards in FY 2017.

The final waiver and project period extension will not exempt the current NACTEP grantees from the appropriation account closing provisions of 31 U.S.C. 1552(a), nor will it extend the availability of funds previously awarded to current NACTEP grantees. As a result of 31 U.S.C. 1552(a), appropriations available for a limited period may be used for payment of valid obligations for only five years after the expiration of their period of availability for Federal obligation. After that time, the unexpended balance of those funds is canceled and returned to the U.S. Department of the Treasury and is unavailable for restoration for any purpose (31 U.S.C. 1552(b)).

Public Comment: In response to our invitation in the proposed waiver and extension, we received 85 comments.

Authority: 35 U.S.C. 207, 37 CFR part 404.

Dated: January 28, 2019.

M.S. Werner,

Commander, Judge Advocate General's Corps, U.S. Navy, Federal Register Liaison Officer.

BILLING CODE 3810–FF–P

DEPARTMENT OF DEFENSE

Department of the Navy

Notice of Public Meetings for the Draft Supplemental Environmental Impact Statement/Overseas Environmental Impact Statement for Mariana Islands Training and Testing

AGENCY: Department of the Navy, DoD.

ACTION: Notice.

SUMMARY: Pursuant to section 102(2)(c) of the National Environmental Policy Act (NEPA) of 1969, as implemented by the Council on Environmental Quality, and Presidential Executive Order (E.O.) 12114, the Department of the Navy (DoN) has prepared and filed with the U.S. Environmental Protection Agency a Draft Supplemental Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS). In the Draft Supplemental EIS/OEIS, the DoN reassesses the potential environmental impacts associated with conducting ongoing and future military readiness activities, which includes training activities and research, development, testing, and evaluation activities (referred to as "testing activities") conducted at sea and on Farallon de Medinilla (FDM) within the Mariana Islands Training and Testing (MITT) Study Area (hereafter referred to as the Study Area) beyond 2020. In the Draft Supplemental EIS/OEIS, the DoN evaluates new, relevant information, such as more recent marine mammal density data and new scientific information, and updates the environmental analyses as appropriate. The DoN prepared the Draft Supplemental EIS/OEIS to support the issuance of federal regulatory permits and authorizations under the Marine Mammal Protection Act and the Endangered Species Act. The National Marine Fisheries Service (NMFS) is a cooperating agency for this Supplemental EIS/OEIS.

DATES: This notice announces the public comment period and the dates and locations of the public meetings, includes information about how the public can review and comment on the document, and provides supplementary information about the environmental planning effort. All comments must be postmarked or received online by March 18, 2019, Chamorro Standard Time, for consideration in the Final Supplemental EIS/OEIS. Federal and local agencies and officials, and interested organizations and individuals, are encouraged to provide substantive comments on the Draft Supplemental EIS/OEIS during the public review period or in person at one of the scheduled open house public meetings.

ADDRESSES: Public meetings will be held in an open-house format, with DoN representatives available to provide information and answer questions related to the Draft Supplemental EIS/OEIS. Open house public meetings will be held on Guam and Saipan. The public may arrive at any time during the open house, as there will not be a presentation or formal oral comment session. Open house public meetings will be held on the following dates and at the following locations:

1. 5:00 to 8:00 p.m. February 26, 2019, at University of Guam, Jesus & Eugenia Leon Guerrero School of Business and Public Administration Building, Anthony Leon Guerrero Multi-Purpose Room 129 and Henry Sy Atrium, Mangilao, Guam 96923.

2. 5:00 to 8:00 p.m. February 27, 2019, at Kanoa Resort Saipan, Seaside Hall, Beach Road in Susupe, Saipan, MP 96950.

Attendees will be able to submit written comments during the open house public meetings. A stenographer will be available for attendees wishing to provide oral comments, one-on-one. Equal weight will be given to oral and written comments. Comments may also be mailed to Naval Facilities Engineering Command Pacific, Attention: MITT Supplemental EIS/OEIS Project Manager, 258 Makalapa Drive, Suite 100, Pearl Harbor, HI 96860–3134, or electronically via the project website at *www.MITT-EIS.com*. All comments, written or oral, submitted during the public comment period will become part of the public record and substantive comments will be addressed in the Final Supplemental EIS/OEIS.

FOR FURTHER INFORMATION CONTACT: Naval Facilities Engineering Command Pacific, Attention: MITT Supplemental EIS/OEIS Project Manager, 258 Makalapa Drive, Suite 100, Pearl Harbor, HI 96860–3134.

SUPPLEMENTARY INFORMATION: The Draft Supplemental EIS/OEIS was distributed to federal and local agencies with which the DoN consulted. Copies of the Draft Supplemental EIS/OEIS are available for public review at the following public libraries:

1. Robert F. Kennedy Memorial Library, University of Guam, UOG Station, Mangilao, GU 96923–1871.

2. Nieves M. Flores Memorial Library, 254 Martyr Street, Hagåtña, GU 96910–5141.

3. Tinian Public Library, San Jose Village, Tinian, MP 96952–9997.

4. Antonio C. Atalig Memorial Library (Rota Public Library), Rota, MP 96951–9997.

5. Joeten-Kiyu Public Library, Insatto Street, Saipan, MP 96950–9996.

The MITT Draft Supplemental EIS/OEIS is available for electronic viewing or download at *www.MITT-EIS.com*. A compact disc of the Draft Supplemental EIS/OEIS will be made available upon written request by contacting: Naval Facilities Engineering Command Pacific, Attention: MITT Supplemental EIS/OEIS Project Manager, 258 Makalapa Drive, Suite 100, Pearl Harbor, HI 96860–3134.

Dated: January 25, 2019.

M.S. Werner,

Commander, Judge Advocate General's Corps, U.S. Navy, Federal Register Liaison Officer.

DEPARTMENT OF DEFENSE

Department of the Navy

Notice of Availability of the Record of Decision for the Final Supplemental Environmental Impact Statement for Land-Water Interface and Service Pier Extension at Naval Base Kitsap Bangor, Kitsap County, WA

AGENCY: Department of the Navy, DoD.

ACTION: Notice.

SUMMARY: The United States Department of the Navy (Navy), announces its decision to construct and operate a Service Pier Extension (SPE) and associated support facilities in Hood Canal on the waterfront of Naval Base (NAVBASE) Kitsap Bangor, Washington (WA). The Navy will implement Alternative 2, short pier configuration, which is the preferred alternative in the October 2018 Final Supplemental Environmental Impact Statement (SEIS) for the Land-Water Interface (LWI) and SPE, NAVBASE Kitsap Bangor, WA. The Alternative 2 short pier configuration is also the environmentally preferred alternative and will fully meet the Navy's purpose and need for the proposed action.

SUPPLEMENTARY INFORMATION: The existing Service Pier will be extended by 520 feet and will require in-water as well as upland construction of

FARM CREDIT SYSTEM INSURANCE CORPORATION

Regular Meeting; Farm Credit System Insurance Corporation Board

AGENCY: Farm Credit System Insurance Corporation.

ACTION: Notice, regular meeting.

SUMMARY: Notice is hereby given of the regular meeting of the Farm Credit System Insurance Corporation Board (Board).

DATES: The meeting of the Board will be held at the offices of the Farm Credit Administration in McLean, Virginia, on January 17, 2019, from 2:00 p.m. until such time as the Board concludes its business.

ADDRESSES: Farm Credit System Insurance Corporation, 1501 Farm Credit Drive, McLean, Virginia 22102. Submit attendance requests via email to *VisitorRequest@FCA.gov.* See **SUPPLEMENTARY INFORMATION** for further information about attendance requests.

FOR FURTHER INFORMATION CONTACT: Dale Aultman, Secretary to the Farm Credit System Insurance Corporation Board, (703) 883–4009, TTY (703) 883–4056, *aultmand@fca.gov.*

SUPPLEMENTARY INFORMATION: Parts of this meeting of the Board will be open to the public (limited space available), and parts will be closed to the public. Please send an email to *VisitorRequest@FCA.gov* at least 24 hours before the meeting. In your email include: Name, postal address, entity you are representing (if applicable), and telephone number. You will receive an email confirmation from us. Please be prepared to show a photo identification when you arrive. If you need assistance for accessibility reasons, or if you have any questions, contact Dale Aultman, Secretary to the Farm Credit System Insurance Corporation Board, at (703) 883–4009. The matters to be considered at the meeting are:

Open Session

A. Approval of Minutes

- December 13, 2018

B. New Business

- Review of Insurance Premium Rates

[1] See the *Notice of Technical Conference* issued on December 12, 2018, for additional details regarding this conference.

EXEMPTIONS PROMULGATED FOR THE SYSTEM:
None.

HISTORY:
February 22, 1993, 58 FR 10227.

DEPARTMENT OF DEFENSE

Office of the Secretary

[Docket ID: DOD–2018–OS–0104]

Submission for OMB Review; Comment Request

AGENCY: Office of the Secretary of Defense, DoD.

ACTION: 30-Day information collection notice.

SUMMARY: The Department of Defense has submitted to OMB for clearance the following proposal for collection of information under the provisions of the Paperwork Reduction Act.

DATES: Consideration will be given to all comments received by April 8, 2019.

ADDRESSES: Comments and recommendations on the proposed information collection should be emailed to Ms. Jasmeet Seehra, DoD Desk Officer, at *oira_submission@omb.eop.gov*. Please identify the proposed information collection by DoD Desk Officer, Docket ID number, and title of the information collection.

FOR FURTHER INFORMATION CONTACT: Angela James, 571–372–7574, or *whs.mc-alex.esd.mbx.dd-dod-information-collections@mail.mil.*

SUPPLEMENTARY INFORMATION:

Title; Associated Form; and OMB Number: Vietnam War Commemoration Program Partner Events; DD Form 2953; DD Form 2954; DD Form 3027; DD Form 3028; DD Form 3029; OMB Control Number 0704–0500.

Type of Request: Extension.

Number of Respondents: 16,020.

Responses per Respondent: 1.8739.

Annual Responses: 30,020.

Average Burden per Response: 15 minutes.

Annual Burden Hours: 7,505.

Needs and Uses: This information collection requirement is necessary to notify the United States of America Vietnam War Commemoration Program of Commemorative Partner's planned events. Information is submitted for inclusion on the program's events calendar and to request event support in the form of materials and/or speakers from the program. The information collection is necessary to obtain, vet, record, process and provide Certificates of Honor to be presented on behalf of a grateful nation by partner organizations. Additionally, this collection is necessary for the partner organizations to communicate to the Commemoration program the results of their events and lessons learned.

Affected Public: Businesses or other for-profits; Not-for-profit institutions; Federal Government; State, local or tribal government, or, by exception, eligible individuals or households.

Frequency: On occasion.

Respondent's Obligation: Voluntary.

OMB Desk Officer: Ms. Jasmeet Seehra.

You may also submit comments and recommendations, identified by Docket ID number and title, by the following method:

- *Federal eRulemaking Portal: http://www.regulations.gov*. Follow the instructions for submitting comments.

Instructions: All submissions received must include the agency name, Docket ID number, and title for this **Federal Register** document. The general policy for comments and other submissions from members of the public is to make these submissions available for public viewing on the internet at *http://www.regulations.gov* as they are received without change, including any personal identifiers or contact information.

DOD Clearance Officer: Ms. Angela James.

Requests for copies of the information collection proposal should be sent to Ms. James at *whs.mc-alex.esd.mbx.dd-dod-information-collections@mail.mil.*

Dated: March 4, 2019.

Aaron T. Siegel,

Alternate OSD Federal Register Liaison Officer, Department of Defense.

DEPARTMENT OF DEFENSE

Department of the Navy

Notice of Rescheduled Public Meetings and Extension of Public Comment Period for the Draft Supplemental Environmental Impact Statement/ Overseas Environmental Impact Statement for Mariana Islands Training and Testing

AGENCY: Department of the Navy, DoD.

ACTION: Notice.

SUMMARY: A notice of public meetings was published in the **Federal Register** by the U.S. Environmental Protection Agency on January 31, 2019 for the Department of the Navy's (DoN) Draft Supplemental Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS) for the Mariana Islands Training and Testing (MITT) Study Area. Due to the effects of Typhoon Wutip, Navy officials postponed public meetings supporting the Draft Supplemental EIS/OEIS planned for February 26–27, 2019.

DATES: This notice announces the dates and locations of the rescheduled public meetings in March 2019, and a 15-day extension of the public comment period from March 18, 2019, to April 2, 2019.

ADDRESSES: Public meetings will be held in an open-house format with DoN representatives available to provide information and answer questions related to the Draft Supplemental EIS/OEIS. The public may arrive at any time during meetings, as there will not be a presentation or public oral comment session. Open house public meetings will be held on the following dates and at the following locations:

1. 1:00 to 3:30 p.m. March 14, 2019, at Tinian Public Library, San Jose Village, Tinian, MP 96952.
2. 1:30 to 4:30 p.m. March 15, 2019, at Mayor's Conference Hall, Songsong Village, Rota, MP 96951.
3. 5:00 to 8:00 p.m. March 18, 2019, at Kanoa Resort Saipan, Seaside Hall, Beach Road in Susupe, Saipan, MP 96950.
4. 5:00 to 8:00 p.m. March 19, 2019, at University of Guam, Jesus & Eugenia Leon Guerrero School of Business and Public Administration Building, Anthony Leon Guerrero Multi-Purpose Room 129 and Henry Sy Atrium, Mangilao, Guam 96923.

Attendees will be able to submit comments during the open house public meetings. Comments may also be mailed to Naval Facilities Engineering Command Pacific, Attention: MITT Supplemental EIS/OEIS Project Manager, 258 Makalapa Drive, Suite 100, Pearl Harbor, HI 96860–3134, or electronically via the project website at *www.MITT-EIS.com*. All comments submitted during the public comment period will become part of the public record and substantive comments will be addressed in the Final Supplemental EIS/OEIS. All comments must be postmarked or received online by April 2, 2019, Chamorro Standard Time, for consideration in the Final Supplemental EIS/OEIS.

Naval Facilities Engineering Command Pacific, Attention: MITT Supplemental EIS/OEIS Project Manager, 258 Makalapa Drive, Suite 100, Pearl Harbor, HI 96860–3134.

SUPPLEMENTARY INFORMATION: The Draft Supplemental EIS/OEIS is available

electronically for public viewing at *www.MITT-EIS.com* and at the following public libraries:

1. Robert F. Kennedy Memorial Library, University of Guam, UOG Station, Mangilao, GU 96923–1871.
2. Nieves M. Flores Memorial Library, 254 Martyr St., Hagåtña, GU 96910–5141.
3. Tinian Public Library, San Jose Village, Tinian, MP 96952–9997.
4. Antonio C. Atalig Memorial Library (Rota Public Library), Rota, MP 96951–9997.
5. Joeten-Kiyu Public Library, Beach Road and Insatto St., Saipan, MP 96950–9996.

Dated: March 1, 2019.

M.S. Werner,

Commander, Judge Advocate General's Corps, U.S. Navy, Federal Register Liaison Officer.

Department of the Navy

Notice of Intent To Grant Exclusive Patent License; Nanocrine, Inc.

AGENCY: Department of the Navy, DoD.

ACTION: Notice.

SUMMARY: The Department of the Navy hereby gives notice of its intent to grant to Nanocrine, Inc., of Frederick, Maryland an exclusive license in the field of use of products and services for use in cell biology research for cell signaling and phenotyping studies and the field of use of products and services for use in cell biology research for cell protein and chemical secretion, in the United States, to U.S. Patent 9,791,368: Nanoplasmonic Imaging Technique for the Spatio-temporal Mapping of Single Cell Secretions in Real Time, Navy Case No. 102,395.//U.S. Patent Application No. 15/784,433: Nanoplasmonic Imaging Technique for the Spatio-Temporal Mapping of Single Cell Secretion in Real Time, Navy Case No, 102,395.//U.S. Patent No. 9,915,654: Light Microscopy Chips and Data Analysis Methodology for Quantitative Localized Surface Plasmon Resonance (LSPR) Biosensing and Imaging, Navy Case No. 101,529.//U.S. Patent Application No. 15/882,081: Light Microscopy Chips and Data Analysis Methodology for Quantitative Localized Surface Plasmon Resonance (LSPR) Biosensing and Imaging, Navy Case No. 101,529.//U.S Patent Application No. 14/039,326: Calibrating Single Plasmonic Nanostructures for Quantitative Biosensing, Navy Case No. 102,043.//U.S Patent Application No. 15/186,742: Determining Extracellular Protein Concentration with Nanoplasmonic Sensors, Navy Case No. 103,502.//U.S. Patent Application No. 16/196,097: Substrates with Indendently Tunable Topographies and Chemistries for Quantifying Surface-Induced Cell Behavior, Navy Case No. 107,399 and any continuations, divisionals, or re-issues thereof.

DATES: Anyone wishing to object to the grant of this license must file written objections along with supporting evidence, if any, not later than March 25, 2019.

ADDRESSES: Written objections are to be filed with the Naval Research Laboratory, Code 1004, 4555 Overlook Avenue SW, Washington, DC 20375–5320.

FOR FURTHER INFORMATION CONTACT: Amanda Horansky McKinney, Head, Technology Transfer Office, NRL Code 1004, 4555 Overlook Avenue SW, Washington, DC 20375–5320, telephone 202–767–1644. Due to U.S. Postal delays, please fax 202–404–7920, email: *techtran@.nrl.navy.mil* or use courier delivery to expedite response.

(Authority: 35 U.S.C. 207, 37 CFR part 404.)

M.S. Werner,

Commander, Judge Advocate General's Corps, U.S. Navy, Federal Register Liaison Officer.

BILLING CODE 3810–FF–P

DEPARTMENT OF ENERGY

Energy Conservation Program for Consumer Products: Representative Average Unit Costs of Energy

AGENCY: Office of Energy Efficiency and Renewable Energy, Department of Energy.

ACTION: Notice.

SUMMARY: In this notice, the U.S. Department of Energy (DOE) is forecasting the representative average unit costs of five residential energy sources for the year 2019 pursuant to the Energy Policy and Conservation Act (Act). The five sources are electricity, natural gas, No. 2 heating oil, propane, and kerosene.

DATES: The representative average unit costs of energy contained in this notice will become effective April 8, 2019 and will remain in effect until further notice.

FOR FURTHER INFORMATION CONTACT: John Cymbalsky, U.S. Department of Energy, Office of Energy Efficiency and Renewable Energy Forrestal Building, Mail Station EE–5B, 1000 Independence Avenue SW, Washington, DC 20585–0121, (202) 287–1692, *ApplianceStandardsQuestions@ee.doe.gov.*

Francine Pinto, Esq. U.S. Department of Energy, Office of General Counsel Forrestal Building, Mail Station GC–33, 1000 Independence Avenue SW, Washington, DC 20585–0103, (202) 586–7432, *Francine.Pinto@hq.doe.gov.*

SUPPLEMENTARY INFORMATION: Section 323 of the Energy Policy and Conservation Act requires that DOE prescribe test procedures for the measurement of the estimated annual operating costs or other measures of energy consumption for certain consumer products specified in the Act. (42 U.S.C. 6293(b)(3)) These test procedures are found in Title 10 of the Code of Federal Regulations (CFR) part 430, subpart B.

Section 323(b)(3) of the Act requires that the estimated annual operating costs of a covered product be calculated from measurements of energy use in a representative average use cycle or period of use and from representative average unit costs of the energy needed to operate such product during such cycle. (42 U.S.C. 6293(b)(3)) The section further requires that DOE provide information to manufacturers regarding the representative average unit costs of energy. (42 U.S.C. 6293(b)(4)) This cost information should be used by manufacturers to meet their obligations under section 323(c) of the Act. Most notably, these costs are used to comply with Federal Trade Commission (FTC) requirements for labeling. Manufacturers are required to use the revised DOE representative average unit costs when the FTC publishes new ranges of comparability for specific covered products, 16 CFR part 305. Interested parties can also find information covering the FTC labeling requirements at *http://www.ftc.gov/appliances.*

DOE last published representative average unit costs of residential energy in a **Federal Register** notice entitled, ''Energy Conservation Program for Consumer Products: Representative Average Unit Costs of Energy'', dated April 24, 2018, 83 FR 17811.

On April 8, 2019, the cost figures published in this notice will become effective and supersede those cost figures published on April 24, 2018. The cost figures set forth in this notice will be effective until further notice.

DOE's Energy Information Administration (EIA) has developed the 2019 representative average unit after-tax residential costs found in this notice. These costs for electricity,

and Recreation Department, Oregon Department of Environmental Quality, Oregon Department of Land Conservation and Development, Oregon Department of State Lands, and Oregon Department of Agriculture.

Alternatives. The EIS will evaluate a no action alternative and action alternatives. The no action alternative is the current management direction for the WVS. Action alternatives will be composed of various measures for continued operations and maintenance of the WVS, as well as measures that will be developed to meet ESA obligations to avoid jeopardizing the continued existence of listed species. Comments received during the scoping comment period will inform the development of action alternatives.

Scoping Process/Public Involvement. The Corps invites all affected federal, state, and local agencies, affected Native American Tribes, other interested parties, and the general public to participate in the NEPA process during development of the EIS. The purpose of the public scoping process is to provide information to the public, narrow the scope of analysis to significant environmental issues, serve as a mechanism to solicit agency and public input on alternatives and issues of concern, and ensure full and open participation in scoping for the Draft EIS. Numerous public scoping meetings will be held during the scoping period. The specific dates, times, and locations of the meetings will be published on the Corps' project website: *https://www.nwp.usace.army.mil/Locations/Willamette-Valley/Evaluation/.*

This is not a notice for the public comment periods for the Cougar Downstream Passage and Detroit Downstream Passage projects; public comment periods for those projects will be noticed separately.

Documents and other important information related to the EIS will be available for review on the Corps' project website.

Aaron L. Dorf,
Colonel, Corps of Engineers, District Commander.

APPENDIX C AGENCY CORRESPONDENCE

This appendix contains correspondence between the Navy and government agencies with respect to cooperating agency status, the Coastal Zone Management Act, the Endangered Species Act, the Essential Fish Habitat Assessment, and the National Historic Preservation Act.

C.1 COOPERATING AGENCY STATUS

C.1.1 NAVY REQUEST LETTER TO THE U.S. COAST GUARD

DEPARTMENT OF THE NAVY
COMMANDER
UNITED STATES PACIFIC FLEET
250 MAKALAPA DRIVE
PEARL HARBOR, HAWAII 96860-3131

IN REPLY REFER TO:
5090
Ser N465/1489
December 13, 2019

RADM Kevin Lunday
Commander, Fourteenth Coast Guard District
300 Ala Moana Blvd FL 9-204
Honolulu, HI 96850-4982

Dear RADM Lunday:

SUBJECT: MARIANA ISLANDS TRAINING AND TESTING SUPPLEMENTAL ENVIRONMENTAL IMPACT STATEMENT/OVERSEA ENVIRONMENTAL IMPACT STATEMENT - COOPERATING AGENCY REQUEST

In accordance with the National Environmental Policy Act (NEPA) of 1969 and Executive Order (EO) 12114, the United States (U.S.) Department of the Navy (Navy) is preparing a Supplemental Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS) to assess the potential environmental impacts associated with the continuation of military readiness activities, which consist of training as well as research, development, testing and evaluation (RDT&E, hereinafter referred to as "testing") activities that include the use of active sonar and explosives in the Mariana Islands Training and Testing (MITT) Study Area. The Navy's purpose of the Proposed Action is to conduct training and testing activities to ensure that the Navy and other Services meet their respective missions, which, for the Navy under Title 10 United States Code (U.S.C.) Section 8062, is to maintain, train, and equip combat-ready military forces capable of winning wars, deterring aggression, and maintaining freedom of the seas.

This MITT Supplemental EIS/OEIS represents the third phase (Phase III) of ongoing NEPA and EO 12114 compliance for continuation of at-sea training and testing. It will evaluate the conduct of military readiness activities from 2020 into the reasonably foreseeable future and accommodate evolving mission requirements associated with force structure changes, including those resulting from the development, testing, and ultimate introduction of new platforms (vessels, aircraft, and weapon systems) into the Fleet.

The Phase III MITT Study Area remains consistent with the area studied in the Phase II MITT EIS/OEIS completed in 2015 and consists of the established at sea ranges, operating areas and special use airspace in the region of the Mariana Islands that are part of the Mariana Islands Range Complex (MIRC) and its surrounding seas, and includes a transit corridor. The transit corridor is outside the geographic boundaries of the MIRC and is a direct route across the high seas for Navy ships in transit between the MIRC and the Hawaii Range Complex. The Proposed

5090
Ser N465/1489
December 13, 2019

Action also includes pierside sonar maintenance and testing alongside Navy piers located in Inner Apra Harbor.

The MITT Phase III Supplemental EIS/OEIS is intended to serve as a basis for the renewal of current regulatory permits and authorizations and the analysis of emerging and future force structure changes and training and testing requirements. An important aspect of the MITT Supplemental EIS/OEIS will be the analysis of the potential effects to marine species protected under the Marine Mammal Protection Act (MMPA) and the Endangered Species Act (ESA) and habitats protected under the Magnuson-Stevens Fishery Conservation and Management Act. The existing MMPA Final Rule and Letters of Authorization for Phase II MITT activities will expire in August 2020.

Pursuant to 40 CFR Section 1501.6, the Navy requests the U.S. Coast Guard's participation in the NEPA process as a cooperating agency.

We appreciate your consideration of our request and look forward to your response. If you require additional information or have questions regarding this project, my points of contact for this matter are Mr. John Van Name, john.vanname@navy.mil, (808) 471-1714 and Ms. Suzanne Smith, suzanne.smith3@navy.mil, (808) 471-4696.

Sincerely,

DANIEL McNAIR
Director, Fleet Environmental Readiness

April 1, 2020

United States Pacific Fleet
Attn: Mr. Daniel McNair
Director, Fleet Environmental Readiness
250 Makalapa Drive
Pearl Harbor, Hawaii 96860-3131

Dear Mr. McNair:

Subject: MARIANA ISLANDS TRAINING AND TESTING SUPPLEMENTAL ENVIRONMENTAL IMPACT STATEMENT/OVERSEA ENVIRONMENTAL IMPACT STATEMENT – COAST GUARD COOPERATING AGENCY ACCEPTANCE

Ref: (a) National Environmental Policy Act (NEPA), 42 U.S.C 4321, et seq.
(b) Council on Environmental Quality Regulations for Implementing the Procedural Provisions of the National Environmental Policy Act, 40 C.F.R. § 1500–1508
(c) Environmental Effects Abroad of Major Federal Actions, Executive Order 12114
(d) U.S. Coast Guard Environmental Planning Policy, COMDTINST 5090.1

The United States Coast Guard (Coast Guard), in response to your letter of 13 December 2019, and in accordance with references (a), (b), and (c), is pleased to accept cooperating agency status with the United States Navy (Navy) as part of the Mariana Islands Training and Testing (MITT) Supplemental Environmental Impact Statement (SEIS)/Overseas Supplemental Environmental Impact Statement (OSEIS). The Coast Guard acknowledges that the Navy is the lead federal agency for SEIS/OSEIS and is primarily responsible for the scope and content of the document. The Coast Guard will participate in the Navy NEPA process as a cooperating agency in order to provide special expertise for Coast Guard training and testing activities analyzed in the SEIS/OSEIS in the MITT study area. The SEIS/OSEIS assesses the potential environmental impacts associated with the continuation of these military readiness activities, which consist of training as well as research, development, testing, and evaluation (RDT&E, hereinafter referred to as "testing") activities that include the use of active sonar and explosives in the MITT study area.

The Coast Guard's actions in the MITT will include surface-to-surface gunnery exercises with small to medium caliber weapons that may include firearms and shoulder line-throwing guns, maritime security operations and civilian port defense using helicopters and vessels to simulate visiting, boarding, and seizing vessels, search and rescue exercises, and precision anchoring training. The purpose of the Coast Guard's actions in the MITT is to ensure effective, close coordination and mission execution between the Navy, Air Force, and Coast Guard operators and assets during actual emergencies and security operations. Joint exercises allow for Navy, Air Force, and Coast Guard commands, operators, and assets to more quickly and effectively respond to threats in the maritime environment and/or prevent such threats.

Subject: MARIANA ISLANDS TRAINING AND TESTING SUPPLEMENTAL ENVIRONMENTAL IMPACT STATEMENT/OVERSEA ENVIRONMENTAL IMPACT STATEMENT – COAST GUARD COOPERATING AGENCY ACCEPTANCE

5090
April 1, 2020

As previously discussed between the Navy and Coast Guard, the Coast Guard intends to adopt the final Navy MITT SEIS/OSEIS (and by SEIS/OSEIS reference the 2015 Navy MITT EIS/OEIS) to provide NEPA compliance coverage for Coast Guard training and testing activities conducted in the MITT and analyzed jointly in the SEIS/OSEIS with Navy and Air Force training and testing activities. The Coast Guard is required by reference (d) to issue and publish a Coast Guard Record of Decision (ROD)/Overseas Decision (OD) when adopting another federal agency's final EIS/OEIS. This Coast Guard policy is based on a similar policy found in the current Department of Homeland Security's NEPA policy.

As a cooperating agency in the MITT SEIS/OSEIS, the Coast Guard agrees to:

a. Participate in the MITT NEPA process;

b. Provide data to the Navy on Coast Guard testing and training activities that take place in the MITT SEIS/OSEIS study area;

c. Assume, on request of the Navy, responsibility for developing information and preparing portions of the SEIS/OSEIS, for which the Coast Guard has special expertise;

d. Provide staff support at the Navy's request to fulfill environmental compliance, consistent with operational and mitigation requirements;

e. Participate, as necessary, in the biweekly meetings hosted by the Navy for discussion of issues related to the SEIS/OSEIS;

f. Provide the draft Coast Guard ROD/OD to Navy for review and comment for a minimum of 10 working days; and

g. Coordinate with Navy on the timing and release of Coast Guard's ROD/OD so that it is synchronized with Navy's ROD release.

The Coast Guard understands that the Navy agrees to:

a. Provide the Coast Guard with a draft final Navy ROD as early as possible in its NEPA process to assist the Coast Guard in the preparation of its own ROD/OD and to facilitate, to the extent appropriate, consistency between the Navy and Coast Guard versions;

b. Provide Coast Guard with comments to Coast Guard's draft ROD/OD within 10 working days of when the Coast Guard submits its draft ROD/OD to Navy;

c. Coordinate with Coast Guard on the timing and publication of Navy's ROD so that Coast Guard can synchronize the publication of its ROD/OD; and

d. Provide the Coast Guard with a copy of the final SEIS/OSEIS.

C.1.3 NAVY REQUEST LETTER TO THE NATIONAL MARINE FISHERIES SERVICE

DEPARTMENT OF THE NAVY
OFFICE OF THE CHIEF OF NAVAL OPERATIONS
2000 NAVY PENTAGON
WASHINGTON DC 20350-2000

5090
Ser N45/17U132422
September 27, 2017

Ms. Donna S. Wieting
Director, Office of Protected Resources
National Marine Fisheries Service
1315 East West Highway
Silver Spring, MD 20910

SUBJECT: MARIANA ISLANDS TRAINING AND TESTING SUPPLEMENTAL ENVIRONMENTAL IMPACT STATEMENT/OVERSEAS ENVIRONMENTAL IMPACT STATEMENT - COOPERATING AGENCY REQUEST

Dear Ms. Wieting:

In accordance with the National Environmental Policy Act (NEPA) of 1969 and Executive Order (EO) 12114, the United States (U.S.) Department of the Navy (Navy) is preparing a Supplemental Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS) to assess the potential environmental impacts associated with the continuation of military readiness activities, which consist of training as well as research, development, testing, and evaluation (RDT&E, hereinafter referred to as "testing") activities that include the use of active sonar and explosives in the Mariana Islands Training and Testing (MITT) Study Area. The proposed training and testing activities within the MITT Study Area supports the Navy's Title 10 of the U.S. Code requirements to achieve and maintain military readiness by ensuring the Navy can provide trained and equipped combat-ready forces capable of winning wars, deterring aggression, and maintaining freedom of the seas.

This MITT Supplemental EIS/OEIS represents the third phase (Phase III) of ongoing NEPA and EO 12114 compliance for continuation of at-sea training and testing. It will evaluate the conduct of military readiness activities from 2020 into the reasonably foreseeable future and accommodate evolving mission requirements associated with force structure changes, including those resulting from the development, testing, and ultimate introduction of new platforms (vessels, aircraft, and weapon systems) into the Fleet.

The Phase III MITT Study Area remains consistent with the area studied in the Phase II MITT EIS/OEIS completed in 2015 and consists of the established at sea ranges, operating areas, and special use airspace in the region of the Mariana Islands that are part of the Mariana Islands Range Complex (MIRC) and its surrounding seas, and includes a transit corridor. The transit corridor is outside the geographic boundaries of the MIRC and is a direct route across the high seas for Navy ships in transit between the MIRC and the Hawaii Range Complex. The Proposed Action also includes pierside sonar maintenance and testing alongside Navy piers located in Inner Apra Harbor.

5090
Ser N45/17U132422
September 27, 2017

The MITT Phase III Supplemental EIS/OEIS is intended to serve as a basis for the renewal of current regulatory permits and authorizations and the analysis of emerging and future force structure changes and training and testing requirements. An important aspect of the MITT Supplemental EIS/OEIS will be the analysis of the potential effects to marine species protected under the Marine Mammal Protection Act (MMPA) and the Endangered Species Act (ESA) and habitats protected under the Magnuson-Stevens Fishery Conservation and Management Act. The existing MMPA Final Rule and Letters of Authorization for Phase II MITT activities will expire in August 2020.

To complete the analysis required by the permitting and consultation process pursuant to MMPA and ESA in an efficient and effective way, the Navy believes that participation by the National Marine Fisheries Service (NMFS) is needed. Therefore, in accordance with the Council on Environmental Quality's (CEQ) regulations implementing NEPA (specifically 40 CFR Part 1501) and CEQ's 2002 guidance on cooperating agencies, the Navy requests that the NMFS serve as a cooperating agency for the development of the Phase III MITT Supplemental EIS/OEIS.

Consistent with 40 CFR 1501.6, the Navy is requesting NMFS' participation as early in the planning process as possible. As the lead agency, the Navy will:

a. Gather all necessary background information and prepare the Phase III Supplemental EIS/OEIS and all necessary permit applications associated with acoustic issues within the Study Area;

b. Work with NMFS personnel to determine the method of estimating potential effects to protected marine species, including threatened and endangered species;

c. Determine the scope of the Phase III MITT Supplemental EIS/OEIS, including the alternatives evaluated;

d. Circulate the NEPA document to the general public and any other interested parties;

e. Schedule and supervise meetings held in support of the NEPA process and compile comments received; and

f. Maintain an administrative record and respond to Freedom of Information Act (FOIA) requests relating to the Phase III Supplemental EIS/OEIS.

Navy respectfully requests that NMFS, in its role as a cooperating agency, provide the following support:

2

5090
Ser N45/17U132422
September 27, 2017

a. Participate in the NEPA process, to include public participation efforts pertaining to the Phase III Supplemental EIS/OEIS, and fund such support through its own sources to the maximum extent possible;

b. Provide timely comments on working drafts of the Phase III Supplemental EIS/OEIS in accordance with the approved project schedule and commenting protocols, and provide minutes of any agency information meeting that have been adjudicated within the agency;

c. Adhere to the overall schedule as set forth by the Navy in coordination with NMFS;

d. Respond to Navy requests for information, in particular, those related to review of the acoustic effects analysis and evaluation of the effectiveness of protection and mitigation measures;

e. Coordinate, to the maximum extent practicable, any public comment periods that are necessary in the MMPA permitting process with the Navy's NEPA public comment periods;

f. Make available staff support at Navy's request to enhance the Navy's interdisciplinary capability;

g. Participate, as necessary, in meetings hosted by the Navy for discussion of issues related to the Phase III Supplemental EIS/OEIS;

h. Utilize NMFS resources, including funding where appropriate, in support of executing its cooperating agency responsibilities.;

i. Prepare any NMFS-specific documents required to support the NMFS decision-making process;

j. Maintain an administrative record and respond to FOIA requests relating to the Phase III Supplemental EIS/OEIS; and

k. Provide a formal, written response to this request.

The Navy views this agreement as important to the successful completion of the environmental planning process for the Phase III MITT Supplemental EIS/OEIS. It is the Navy's goal to complete the analysis as expeditiously as possible, while using the best scientific information available. NMFS assistance is invaluable to this endeavor.

C.1.4 NATIONAL MARINE FISHERIES SERVICE RESPONSE LETTER

UNITED STATES DEPARTMENT OF COMMERCE
National Oceanic and Atmospheric Administration
NATIONAL MARINE FISHERIES SERVICE
Silver Spring, MD 20910

Captain C.A. Lahti
Director, Energy and
Environmental and Readiness Division
Department of the Navy
2000 Navy Pentagon
Washington, DC 20350-2000

Dear Captain Lahti:

Thank you for your letter requesting the National Marine Fisheries Service (NOAA Fisheries) be a cooperating agency in the preparation of a Supplemental Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS) to evaluate potential environmental effects in the Department of the Navy's (Navy) Mariana Islands Training and Testing (MITT) Study Area. Activities conducted in the MITT Study Area will achieve and maintain military readiness and include current, emerging, and future training activities and research, development, test and evaluation events (Phase III). We support the Navy's decision to prepare a Supplemental EIS/OEIS on this activity and agree to be a cooperating agency, due, in part, to our responsibilities under section 101(a)(5)(A) of the Marine Mammal Protection Act and under section 7 of the Endangered Species Act. NOAA Fisheries will make every effort to support the Navy in the development of a Supplemental EIS/OEIS, including:

- Participating, as necessary, in meetings hosted by the Navy for the discussion of issues related to the Phase III Supplemental EIS/OEIS;
- Providing timely comments on working drafts of the Phase III Supplemental EIS/OEIS in accordance with the approved project schedule and commenting protocols;
- Responding to Navy requests for information, in particular, those related to review of the acoustic effects analysis and evaluation of the effectiveness of protection and mitigation measures; and
- Adhering to the overall schedule as set forth by the Navy in coordination with NMFS.

If you need any additional information, please contact Jolie Harrison at (301) 427-8420.

Sincerely,

Samuel D. Rauch III
Deputy Assistant Administrator for

Ser N465/1491
December 16, 2019

Mr. Arthur Charsauros
Director
Division of Coastal Resources Management
Bureau of Environmental and Coastal Quality
P.O. Box 501304, Saipan, MP 96950

Dear Mr. Charsauros:

SUBJECT: CONSISTENCY DETERMINATION FOR MILITARY TRAINING AND TESTING WITHIN THE COASTAL ZONE OF THE COMMONWEALTH OF THE NORTHERN MARIANA ISLANDS

In accordance with the Federal Coastal Zone Management Act and 15 C.F.R. § 930, the U.S. Navy submits the enclosed Federal Consistency Determination (CD) for proposed activities in the Mariana Islands Training and Testing (MITT) Study Area that have reasonably foreseeable coastal effects on the coastal zone of the Commonwealth of the Northern Mariana Islands (CNMI).

Based on the enclosed consistency assessment and the activities and analysis contained in the enclosed Draft Supplemental Environmental Impact Statement/Overseas Impact Statement (DSEIS/OEIS), the Navy finds that the proposed military training and testing activities presented in Alternative 2 are consistent to the maximum extent practicable with the enforceable policies of the CNMI Coastal Resource Management Program.

If you have any questions, please contact Mr. John Van Name at (808) 471-1714 or john.vanname@navy.mil or Ms. Suzanne Smith at (808) 471-4696 or suzanne.smith3@navy.mil.

Sincerely,

DANIEL McNAIR
Director, Fleet Environmental Readiness
By direction of the Commander

Re: Consistency Determination for Military Training and Testing Within the Coastal Zone of the Commonwealth of the Northern Marianas Islands (CNMI)

Dear Mr. Van Name and Ms. Smith,

The Commonwealth of the Northern Mariana Islands' (CNMI) Division of Coastal Resources Management (DCRM) has reviewed the U.S. Department of the Navy's Federal Consistency Determination (CD) submitted and received by our office on December 17, 2019 for the proposed activities in the Marianas Islands Training and Testing (MITT) Study Area within the Coastal Zone of the CNMI.

After carefully reviewing this CD, and as outlined further herein, DCRM finds that the proposed MITT activities as reflected in Alternative 2 of the Draft Supplemental Environmental Impact Statement / Overseas Impact Statement (DSEIS/OEIS) are not consistent with the enforceable policies of the CNMI Coastal Management Program. Therefore, DCRM recommends the Department of the Navy revise its CD to address data gaps, including inconsistencies and lack of up-to-date data, as well as detail and include further mitigation of potential effects on the CNMI's coastal resources.

To support DCRM's CD response, comments from both divisions under the Bureau of Environmental and Coastal Quality (BECQ) as well as the public comments received during the extended public commenting period of 30 days are enclosed and incorporated by reference here. Comments raised concerns that DCRM shares regarding the lack of inclusion of land-based training activities in this CD as it appears from the draft Environmental Impact Statement (DEIS) that changes in land-based training are indeed proposed.

The government of the CNMI recognizes the important training needs of the U.S. Military and hopes to accommodate those needs in a manner that is consistent with the federally approved coastal management policies of the CNMI Coastal Management Program. We look forward to the opportunity to discuss our concerns and how consistency with the policies of the CNMI Coastal Management Program can be achieved to the greatest extent practicable.

As detailed further herein, DCRM finds that the current DEIS/OEIS MITT proposal is not consistent with the enforceable policies of the CNMI Coastal Management Program as the submitted information is not sufficient for a complete and adequate analysis. In fact, it is not entirely evident from current submissions what mitigation measures are being proposed for review. Although Section 930.37 of Federal Consistency regulations provide for use of a DEIS to support a consistency determination, "a Federal agency's federal consistency obligations under the Act are independent of those required under NEPA and are not necessarily fulfilled by the NEPA document." As such, references to mitigation measures or conservation recommendations that will be implemented as results from initiated Endangered Species Act (ESA) and Marine Mammal Protection Act (MMPA) consultations cannot be considered as part of this CD as they have not yet been completed.

In order for MITT activities to achieve consistency with CNMI's enforceable policies, it is essential that the Navy clearly outline existing conditions, rigorously assess effects, and detail what monitoring and mitigation efforts will be implemented. It is encouraged that critical data gaps including lack of baseline information relating to water quality, species diversity and abundance within the training areas including wildlife populations around Saipan, Farallon de Medinilla (FDM), Tinian, and Rota be addressed through additional studies designed if not implemented in coordination with CNMI and that resulting data be shared in a timely manner to support review. As outlined in the Consistency with Enforceable Policies section of this letter, additional information is needed on the following items in order to assess the consistency of the MITT with the CNMI enforceable policies:

NMIAC § 15-10

- **Part 300 - Standards for CRM Permit Issuance**
  § 15-10-301, General Standards for all CRM Permits
  § 15-10-305, Standards for DCRM Permit Issuance General Criteria
  § 15-10-315, Specific Criteria; Areas of Particular Concern; Lagoons and Reefs
  § 15-10-325, Specific Criteria; Areas of Particular Concern; Coral Reefs
  § 15-10-335, Specific Criteria; Areas of Particular Concern; Shorelines
  § 15-10-340, Specific Criteria; Areas of Particular Concern; Ports and Industrial Areas:

  Provide substantial details as to why each of these Areas of Particular Concern (APC) will not be affected by the direct, indirect, or cumulative effects from the proposed activities including analysis of potential spillover impacts.

- **Part 500 - Standards for Determining Major Siting**
  § 15-10-501, Determination of Major Siting
  § 15-10-505, Specific Criteria for Major Siting

  Part 600 - CRM Permit Conditions

  Provide substantial details as to why the Navy's Proposed Action does not meet the criteria for a Major Siting, and analysis regarding how the Proposed Action would

otherwise not have the potential to directly and significantly impact CNMI coastal resources with the potential for significant adverse effects .

Division of Environmental Quality (DEQ) Water Quality Standards: Classification and Establishment of Water Use Areas and Specific Water Quality Criteria

Data has not been provided to confirm baseline water quality in areas of proposed activities or to substantiate statements that there are no reasonably foreseeable effects. To achieve consistency please provide literature cited in the CD as well as any recent scientific studies which contain current and accurate scientific data and clear impacts criteria for direct and cumulative impacts incorporated into the CD analysis on water quality. If such data is lacking for activities in the study area, reasonable efforts to conduct such data collection and assessments to demonstrate that CNMI waters are kept "shall be free from toxic pollutants in concentrations that are lethal to, or that produce detrimental physiological responses in human, plant, or animal life" should be undertaken.

CNMI Public Law No. 3-47; Policy Elements 4, 10, 11, 12, 13, 15, 16, 17 & 21:

Provide a timeline, detailed analysis, and sufficient data for the discussion of mitigation measures outlined throughout these policy elements. To be consistent with enforceable policies of the CNMI, the Navy needs to specify monitoring and mitigation – including providing reasonable details regarding *how and when* impacts will be mitigated – and provide implementation timelines to ensure impacts of these activities are in fact being avoided, minimized, and mitigated to the greatest extent practicable.

Provide current detailed analysis and sufficient data for all applicable coastal resources, particularly coral and algae diversity, cover, and structural complexity; especially for ESA-listed corals in critical areas such as those listed in MITT Draft Supplemental EIS/OEIS Vol. 2 sites on Tinian (Unai Babui, Unai Dankulu, and Unai Chulu), and where training areas will overlap with nearshore habitats.

Provide current data or modeling that determines that emissions from the proposed activity will not lead to a violation of National Ambient Air Quality standards (NAAQS) in the coastal zones of Saipan, Tinian, and Rota. Please see attached BECQ comments for an in-depth description of these policy elements.

It is also critical that the Navy takes steps to provide meaningful analysis of data and standards of DCRM's enforceable policies. Details and analysis deficiencies noted in received comments that DCRM hopes the Navy can remedy include the following:

- **Policy Element 4** – "Plan for and manage any use or activity with the potential for causing a direct and significant impact on coastal resources. Significant adverse impacts shall be mitigated to the extent practicable."

  The Coastal Zone Management Act broadly defines the environment. Instead of considering impacts of increased activities to the people of the CNMI and the coastal

resources that comprise our home, the CD narrowly discusses potential impacts to marine mammals, coral, and fishes in water and does not reassess impacts of land-based activities on Saipan, Tinian, and Rota or FDM, stating that no changes in these activities are proposed. As previously mentioned, FDM activities appear to be significantly increasing, and mitigation measures proposed by DCRM to ensure consistency with land-based operations in the 2015 MITT do not appear to have been implemented regularly – particularly as they pertain to early coordination and data sharing with CNMI. It is unclear why the Navy states that mitigation measures are outside of the scope of this SEIS/OEIS (CD enclosure pg. 23), especially given the fact that the 2014 CD correspondence from DCRM noted that "[i]n order to comply with the enforceable polices of the CNMI, further measures are needed to protect the wildlife and habitats of the CNMI."

Similarly, in this CD request like the 2014 submission, the basis for finding that the MITT is consistent to the maximum extent practicable has not been established. The Navy must show how its proposed actions are fully consistent by providing data, not speculative conclusions such as that potential effects to endangered species will be addressed through pending biological opinions. As also noted previously, the statement that the "Navy's Proposed Action provides special protection to coastal resources and mitigates adverse impacts" is inadequate to demonstrate consistency as the SEIS/OEIS does not actually commit to mitigation measures or timelines for implementation of mitigation, making these assurances rather hollow and unenforceable. If the Navy plans to rely on the suite of mitigation options discussed in the Draft SEIS/OEIS to demonstrate compliance with CNMI's enforceable policies including the requirement of mitigation of adverse impacts, meaningful and enforceable commitments and timelines for implementation should be developed as part of this CD correspondence.

- **Policy Element 10** – "Maintain or improve coastal water quality through control of erosion, sedimentation, runoff, siltation, sewage and other discharges."

  Assessment of this policy element and supporting regulations is inadequate and this analysis should be revised to support DCRM's review of this CD request.

- **Policy Elements 11 and 12** – Impacts to cultural resources.

  Although Section 106 consultations are ongoing to support the reissuance of the expired Programmatic Agreement, the analysis of impacts to cultural resources referenced in Section 3.11 of the draft SEIS/OEIS does not include sufficient data to make any determination regarding likely significant impacts to cultural resources within CNMI waters and on FDM. Absence of evidence is not evidence of absence and the DoD has an obligation to implement reasonable assessment of resources that are likely to be impacted by MITT activities. Lacking that data, there is therefore no basis for the Navy's conclusion that this proposed action is consistent with these policy elements. Data gaps should be remedied to ensure consistency with these policies and the CNMI's significant and compelling interest to protect and preserve our cultural resources.

Doc. No. 35GL-20-1874.*

- **Policy Element 13** – "Require compliance with all local air and water quality laws and regulations and any applicable federal air and water quality standards."

  Data must be provided to support the conclusory statements that air emissions will be minimal on Saipan and Rota and will be "intermittent and short term, resulting in minimal impact on the air quality of Tinian". Models are available to assess these activities for compliance with local and federal air quality standards and should be included for review in this submission. Comments regarding water quality standards are incorporated by reference here.

- **Policy Elements 15 and 16** – Management of marine resources and consistency with other policies.

  As noted in the response to Policy Element 4, the Navy's analysis of impacts to coastal resources is overly narrow and does not meaningfully address impacts to the human environment. This is especially true regarding impacts to the integrity of our reefs and wildlife habitat (Policy 15) and the management and development of our local subsistence, sport, and commercial fisheries (Policy 16). The draft SEIS/OEIS contains insufficient assessment of the potential impacts to these resources and the "analysis" under Policy Element 4 does not address potential impacts to human uses such as fishing and traditional access to important fishing areas. Thus, it is unclear how the Navy can conclude their proposed actions are consistent when analysis is completely lacking. An updated CD should address this gap, preferably through a revised SEIS that provides meaningful analysis of impacts to these important coastal resources.

- **Policy Element 17** – "Protect all coastal resources, particularly sand, coral and fish from taking beyond sustainable levels and in the case of marine mammals and any species on the Commonwealth endangered species list, from any taking whatsoever."

  The Navy explains that "the Proposed Action has the potential to take marine mammals and species on the Commonwealth endangered species list" and that "[a]ny take occurring as a result of the Proposed Action would be incidental to, and not the purpose of, the Navy's otherwise lawful training and testing activities" and notes that protective measures intended to avoid and minimize the "take" of endangered species will be updated as appropriate upon completion of the Section 7 consultation. As noted previously, past promises of mitigation and monitoring have not been executed, or, if they have been, have not been shared with the CNMI, therefore, it is encouraged that any monitoring and mitigation agreements that are the basis for a consistency determination include timebound deliverables so that consistency can be demonstrated.

- **Policy Element 21** – "Encourage the preservation of traditional rights of public access to and along the shorelines consistent with the rights of private property owners."

  Contrary to the Navy's statement that the "MITT Draft Supplemental EIS/OEIS does not propose any change to the public access normally allowed on federally leased lands including FDM, which would remain restricted for security and safety reasons" and that

the "MITT Draft Supplemental EIS/OEIS does not propose a change to the ocean areas currently used by both the Navy and the public", increases in the intensity and use of CNMI lands and waters is more likely than not to have significant impacts to public access of shorelines and traditional fishing areas. Already, three nautical miles (nm) surrounding the abundant fishery surrounding FDM is periodically restricted and this SEIS proposes to extend that "danger zone" to 12 nm and increase the frequency of restricted use in this area. These restrictions can have direct and significant impacts to boaters and the fishing community by increasing travel time and forcing seagoing vessels to travel well out of their traditional navigation routes. Similarly, periodic exercises on Tinian significantly restrict community access to forests and shorelines that have been traditionally used for subsistence and commercial activities. The frequency and timing of these restrictions should be discussed further with the CNMI in order to maximize access for users of these ocean resources while ensuring the Navy can meet its training objectives. Given that assessment of impacts and commitment to reasonable mitigation measures are lacking in the SEIS/OEIS, meaningful commitments should be articulated in supplemental analysis in a revised CD in order to ensure consistency with this enforceable policy.

Consistency with Enforceable Policies

The CNMI has determined the MITT is inconsistent with the enforceable policies of the CNMI Coastal Management Program in the following ways:

NMIAC § 15-10 Part 300 - Standards for CRM Permit Issuance
§ 15-10-301, General Standards for all CRM Permits
§ 15-10- 305, Standards for DCRM Permit Issuance General Criteria

As stated in the CD, "Not Applicable. The Navy's Proposed Action does not include applying for permits with the CNMI". However, if these sections are not applicable, further details explaining why these proposed actions do not apply should be outlined to frame discussion regarding their applicability to DCRMs enforceable policies.

NMIAC § 15-10 Part 300 - Standards for CRM Permit Issuance
§ 15-10-315, Specific Criteria; Areas of Particular Concern; Lagoons and Reefs
§ 15-10-325, Specific Criteria; Areas of Particular Concern; Coral Reefs
§ 15-10-335, Specific Criteria; Areas of Particular Concern; Shorelines
§ 15-10-340, Specific Criteria; Areas of Particular Concern; Ports and Industrial Areas

The information stated in the CD does not provide substantial details as to why these Areas of Particular Concern (APC) will not be affected by the direct, indirect, or cumulative effects from the proposed action. DCRM has previously commented on portions of the Draft Supplemental Environmental Impact Statement/Overseas Impact Statement (DSEIS/OEIS), requesting best available scientific data and clear impacts criteria for direct, indirect and cumulative impact analysis. The current data outlined in the CD does not support meaningful analysis of the impacts and possible mitigation of these impacts.

Doc. No. 35GL-20-1874.*

NMIAC § 15-10 Part 500 - Standards for Determining Major Siting
§ 15-10-501: Determination of Major Siting
§ 15-10-505: Specific Criteria for Major Sitings

NMIAC § 15-10 Part 600 - CRM Permit Conditions

As stated in the CD, "Not Applicable. The Navy's Proposed Action does not meet the criteria for a major siting." Under the CNMI's enforceable policies, a "major siting" is defined as "any proposed project which has the potential to directly and significantly impact coastal resources" including "proposed projects with potential for significant adverse effects on submerged lands,…reefs, wetlands, beaches and lakes…and endangered or threatened species or marine mammal habitats" (§15-10-020(uu)(4)). Consistency with major siting standards of §15-10-505 should be assessed, especially in terms of how training and testing activities will affect the broadly defined coastal environment including fish and wildlife habitat, cultural resources, and the natural integrity of CNMI water bodies and what mitigation responses will be implement to ensure impacts are avoided, minimized, and mitigated. Moreover, based on the lack of data, substantive details, and meaningful analysis in the CD regarding the impacts to these coastal resources, DCRM believes the proposed MITT activities are likely to have significant adverse effects on the CNMI's coastal resources. Meaningful analysis of data and standards of enforceable policies are necessary to support a review of proposed activities to ensure consistency and should be included in revised documentation to facilitate this effort.

DEQ Water Quality Standards: Classification and Establishment of Water Use Areas and Specific Water Quality Criteria

The information stated in the CD does not provide critical details to adequately address DEQ Water Quality Standards. The literature cited is not included in full detail in the CD, and it appears that DoD has collected no water quality sampling, monitoring, or analysis within the Marianas Islands Range Complex. Additionally, information cited from the previous MITT does not provide current and accurate scientific data and clear impacts criteria for direct and cumulative impacts related to water quality. To ensure consistency, it is recommended that the Navy develop and implement a monitoring plan to ensure water quality stays within CNMI standards. To provide baseline data necessary to substantiate the conclusion that activities have had and will continue to have "no effects" on water quality, it is strongly encouraged that the Navy take reasonable steps to provide additional data on bio-accumulation of toxins associated with ordinance in marine life and localized effects within the monitoring plan, including assessment of fish and filter-feeding invertebrates around Saipan, FDM, Tinian, and Rota.

CNMI Public Law No. 3-47; Policy Elements 4, 10, 11, 12, 13, 15, 16, 17 & 21:

The information stated in the CD does not provide substantial details and data to adequately address Policy Elements 4, 10, 11, 12, 13, 15, 16, 17 & 21. Currently the CD does not look at the combined impacts of the MITT with other military activities in the study area and therefore does not present adequate information on direct, indirect, or cumulative impacts. There is also limited information regarding the duration, temporal, and spatial context of proposed activities, and

whether activities will occur in separate or simultaneous locations and times – critical details when discussing the context and intensity and therefore the "significance" of a proposed action and its effects. DCRM holds that additional information regarding proposed activities and mitigation measures are needed in order to comply with the enforceable policies of the CNMI.

Review Standards for Federal Consistency

Under the Coastal Zone Management Act (CZMA) of 1972, 16 USC § § 1451-1465, § 1456(c)(1), and Federal Consistency regulations, 15 CFR § § 930.30-930.46, Federal agency activities with reasonably foreseeable effects on the State's coastal zone must be consistent to the maximum extent practicable with the enforceable policies of the States' federally approved CZMA programs. Under 15 CFR §930.32(a)(1), the standard for "consistent to the maximum extent practicable" means fully consistent with the enforceable policies of the CNMI's management programs unless full consistency is prohibited by existing law applicable to the Federal agency. Thus, the Navy must show how existing law prohibits full consistency with the CNMI's Coastal Management Program. However, the Navy has not provided any description of any statutory provisions, legislative history, or other legal authority which limits the Navy's discretion to be fully consistent with the enforceable policies of CNMI's management program.

Furthermore, 15 CFR §930.32(a)(2) details that 16 USC § 1456(e), "construction with other laws", or "Section 307(e) of the Act does not relieve Federal agencies of the consistency requirements under the Act. The Act was intended to cause substantive changes in Federal agency decision making within the context of the discretionary powers residing in such agencies. Accordingly, ***whenever legally permissible, Federal agencies shall consider the enforceable policies of management programs as requirements to be adhered to in addition to existing Federal agency statutory mandates***. If a Federal agency asserts that full consistency with the management program is prohibited, it shall clearly describe, in writing, to the State agency the statutory provisions, legislative history, or other legal authority which limits the Federal agency's discretion to be fully consistent with the enforceable policies of the management program" (emphasis added).

As such, if there are impediments to achieving consistency as outlined here, DCRM encourages the Navy to work with the CNMI through the Bureau of Military Affairs and our office to discuss and remedy these challenges. Lacking such restraints, CNMI encourages the Navy to provide the requisite details to demonstrate full consistency with all applicable DCRM enforceable policies including:

- Full consistency with local permitting considerations;
- Application of CD analysis to all relevant enforceable policies;
- Reasonable collection and analysis of relevant data and standards to support assessment of impacts; and
- Time-bound commitments to proposed mitigation measures that will be implemented to ensure consistency to the maximum extent practicable.

In conclusion, insufficient information has been provided in this CD for DCRM to agree that the MITT activities are consistent with the CNMI's rules and regulations. Given these challenges, it would seem prudent that the Navy consider coordinating with the CNMI to address data gaps

further and submitting a revised Consistency Determination Request after an updated Final Supplemental EIS has been circulated and comments have been received and reviewed. The Coastal Zone Management Act does provide for flexibility in timelines to support robust review of impacts to coastal resources, and DCRM would welcome the opportunity to discuss a mutually agreeable timeline for revisions or resubmission of this determination request when a preferred alternative has been selected.

To achieve consistency with CNMI's enforceable policies, the Department of the Navy will need to modify its MITT proposal to provide reasonably sufficient details to support analysis as to why each of these sets of proposed actions will not cause significant direct, indirect, and/or cumulative effects including spillover impacts on the CNMI's coastal resources. Additionally, DCRM would welcome further clarification and discussion of specific mitigation measures and alternatives proposed by the Navy to support your timelines and ensure adverse impacts are being appropriately mitigated. The CNMI recognizes the critical mission and ongoing training needs of the U.S. Military and looks forward to discussing ways the MITT can become consistent with the CNMI's enforceable policies.

Please note the included comments from CNMI Bureau of Environmental and Coastal Quality, as well as public comments which are attached to this consistency determination. Should you have any questions or require further information, please contact (670) 664-8308 or fedcon@dcrm.gov.mp.

Sincerely,

JANICE E. CASTRO
Director
Division of Coastal Resources Management

CONSISTENCY DETERMINATION FOR COMMONWEALTH OF THE NORTHERN MARIANA ISLANDS

PUBLIC LAW No. 3-47

Policy Element 4. *Plan for and manage any use or activity with the potential for causing a direct and significant impact on coastal resources. Significant adverse impacts shall be mitigated to the extent practicable.*

Policy Element 15. *Manage ecologically significant resource areas for their contribution to marine productivity and value as wildlife habitats, and preserve the functions and integrity of reefs, marine meadows, salt ponds, mangroves and other significant natural areas.*

Policy Element 17. *Protect all coastal resources, particularly sand, coral and fish from taking beyond sustainable levels and in the case of marine mammals and any species on the Commonwealth endangered species list, from any taking whatsoever.*

Comment:

In regards to Public Law No.3-47, Policy Elements 4, 15, and 17, the impact on coastal resources, specifically coral reefs, is not adequately addressed. Table 1 of the consistency document lists several activities that will occur in the Marianas littorals and Tinian, which will overlap fringing reefs. Section 3.8-11 of the MITT Draft Supplemental EIS/OEIS Vol. 2 lists beaches on Tinian (Unai Babui, Unai Dankulu, and Unai Chulu), where training areas will overlap nearshore habitats and states:

"However, the combined consequences of all physical disturbance and strike stressors could degrade habitat quality at some locations. As stated above, combat swimmers and Marines may be required to walk through nearshore areas and reefs during these activities, potentially causing damage to coral species. As stated in the 2015 MITT Final EIS/OEIS and above, these activities could cause injury or mortality to individuals, but impacts on marine invertebrate populations, including ESA-listed corals, are unlikely."

Since the distribution of ESA-listed corals in the Marianas has not been mapped out, the statement that impacts to marine invertebrate populations and ESA-listed corals is not supported. We do share many coral species with other Pacific reefs, however, the Marianas region is isolated in terms of genetic connectivity to the rest of Micronesia, where the majority of coral and fish larvae originate from Saipan and Tinian (Kendall & Poti, 2014; Maynard et al., 2015; Randall, 1995). Therefore, any physical disturbance through accidental damage on reef structure can impede recovery for the coral reefs of the CNMI that are still recovering from mass bleaching events, two category 5 typhoons, and multiple crown-of thorns outbreaks.

In addition, assessing species or population level impacts of marine invertebrate populations for shallow coral reefs provides an incomplete analysis on the environmental impacts for our region. Coral and algae diversity, cover, and structural complexity are also important indicators of reef ecosystem function and health. The CNMI has suffered severe coral mortality from back to back bleaching events in 2013, 2014, 2016, and 2017 (Heron et al., 2016; Reynolds et al., 2014). For example, Unai Babui in Tinian is designated as a training area in the MITT EIS, and is one of CRM's long-term marine monitoring sites since 2001. Since 2009, Unai Babui has had a steady decline in coral cover with a large increase in macroalgae cover, and loss in crustose coralline algae (CCA). CCA is extremely important in

strengthening reef structure and are resistant to ocean acidification (Nash et al., 2013; Nelson, 2009). Coral cover at Unai Babui is hovering at less than 10% and for Unai Dankulu at less than 15% in 2018. Maintaining coral cover above 10% is a critical threshold for sustaining reef function (Darling et al., 2019). The shallow water reefs around Tinian are already vulnerable from past storm and bleaching disturbances, and decline in coral cover is now at a critical threshold where further loss can severely reduce chances of recovery. In addition, any damage to reef structure, whether live or dead coral, will degrade habitat quality by accelerating reef breakage and loss of structural complexity, resulting in loss of habitat for diverse species, potential loss of storm protection, and accelerates erosion of the reef. Therefore, proposed listed actions in Table 1, for the Mariana littoral zone and Tinian are not sustainable and would further put CNMI's coastal resources at risk of further degradation.

December 2019 Consistency Determination
Air Quality Comments – Larry Maurin

COASTAL ZONE MANAGEMENT ACT – CONSISTENCY DETERMINATION FOR COMMONWEALTH OF THE NORTHERN MARIANA ISLANDS

Public Law No. 3-47

Policy Element 13. Require compliance with all local air and water quality laws and regulations and any applicable federal air and water quality standards.

Page 24: Comments on Air Quality Impacts of the Proposed Action

- Air quality impacts of criteria and hazardous air pollutants from additional activities in the Proposed Action (i.e. Phase III) have not been quantified and included in the consistency determination, so the 2015 MITT Final EIS/OEIS is not representative of cumulative air emissions.
- Emissions of criteria and hazardous air pollutants that may affect the Rota and Saipan Coastal Zones have not been quantified, and no modeling has been done to determine if these emissions will lead to a violation of the National Ambient Air Quality Standards (NAAQS) and CNMI Ambient Air Quality Standards. There must be a basis for the claim that "air quality impacts attributable to the military training and testing activities" to the Saipan and Rota coastal zone "uses and resources would be minimal." No basis for this claim has been presented.
- Additional emissions of criteria and hazardous air pollutants from Phase III activities that may affect the coastal zone of Tinian have not been quantified. There must be a basis for the claim that "combined effects from air quality impacts attributable to the military training and testing activities to the Tinian coastal zone uses and resources would be minimal." No basis for this claim has been presented.
- There must be a basis for the claim that "the Proposed Action complies with all local air quality laws and regulation and any applicable federal air quality standards". No quantification of additional impacts from Phase III has been conducted and no modeling analysis has been submitted to ensure compliance with the NAAQS and CNMI Ambient Air Quality Standards.
- There must be a basis for the statement that "air emissions generated as a result of the Proposed Action would be minimal, intermittent, and short term. Thus, the Proposed Action would not have a significant impact on ambient air quality and is in compliance with local and federal air quality standards." No modeling analysis of the Proposed Action has been submitted to demonstrate that there would be no significant impact on the NAAQS or CNMI Ambient Air Quality Standards.

Comments - Military Training and Testing within the CZ of the CNMI Kathy Yuknavage

DESCRIPTION OF THE PROPOSED ACTION

Page: 2

Navy states that, "These training and testing activities include the use of active sonar and explosives at sea in the MIRC (the Navy is not proposing to use explosives at sea within the CNMI coastal zone)."

The use of sonar and explosives at sea around the MIRC and the transit corridor between the MIRC and the Hawaii Range Complex is of concern due to potential impacts to Cetacea and other aquatic mammals and organisms. These waters and those of the Marianas Trench Monument are high quality waters of ecological significance that provide an important migration marine corridor and breeding ground for these species. The Department of the Navy states that these 'active sonar and explosives at sea' will not cause harm to these or other aquatic life, without citing specific data from peer reviewed or defensible research studies.

It should also be noted that these marine species are important not only to the CNMI tourist economy, but also to the international community where they are known to migrate to, and from.

The CNMI Water Quality Standards (WQS) antidegradation policy states that, "Tier 3: ***High quality waters*** which constitute an outstanding Commonwealth resource, such as waters of National Parks, marine sanctuaries, wildlife refuges and ***waters of exceptional recreational or ecological significance shall be maintained and protected. Actions which would lower water quality in such waters are prohibited***, with the exception of temporary degradation deemed necessary for the construction of important Park infrastructure, pollution control devices, and BMPs designed to improve water quality.".

Pages: 3 - 4

The Navy states that for both the Islands of Tinian and Rota that, "Only those activities that are new and include the use of sonar are analyzed in this Consistency Determination. Other activities that include the use of sonar were previously analyzed in the 2014 Consistency Determination document, which determined the ***Proposed Action was consistent to the maximum extent practicable with applicable enforceable policies***."

Please define 'maximum extent practicable with applicable enforceable policies.'. Whose policies are these?

Provide evidence that no other alternatives could be used for tracking other than sonar in these waters given that recent studies have found sonar to have serious detrimental impacts on whales feeding modes and behavior. (2016. "Impacts of Sonar on Marine Mammals", SERDP ESTCP.; 2013. Goldbogen, et.al., "Blue whales respond to simulated mid-frequency military sonar": https://doi.org/10.1098/rspb.2013.0657; 2000. ECM Parsons, "Impacts of Navy sonar on whales and dolphins: Now beyond a smoking gun?" Env. Sci, and Policy, George Mason Univ. VA).

DEPARTMENT OF ENVIRONMENTAL QUALITY WATER QUALITY STANDARDS: CLASSIFICATION AND ESTABLISHMENT OF WATER USE AREAS AND SPECIFIC WATER QUALITY CRITERIA

Page: 16

The Navy states that, "the majority of concerns regarding bioaccumulation are associated with urban coastal environments with specific point source and non-point source contributors of pollutants. ***The studies concerning military sites suggest that metals exposed to seawater are of less concern because of decreased bioavailability***."

There are still concerns regarding bioaccumulation of heavy metals and toxins from munition constituents associated with on-going live fire and bombing ranges.

Which studies are being discussed? None are cited to defend this claim. Please provide scientifically defensible research to support this statement.

Page: 17

The Navy states that, "activities occurring beyond the CNMI coastal zone would not affect the land or water use, or natural resource of the coastal zone because **(1) most of the explosives would be consumed during detonation; (2) the frequency of low-order detonations would be low, and therefore the frequency of releases of explosives would be low; (3) the amounts of explosives used would be small relative to the area within which they would be distributed; and (4) the constituents of explosives would be subject to physical, chemical, and biological processes that would render the materials harmless or otherwise disperse them to undetectable levels**." This section sites the "2015 MITT Final EIS/OEIS as containing a detailed analysis of fate and transport of byproducts produced during military training and testing activities".

This citation from an EIS, produced five years ago is insufficient to substantiate the above claim. The findings from the MITT analysis that defends claims (1) – (4) should be described herein for new reviewers and to refresh those that took part in reviewing previous EIS and Federal Consistency Determinations. Specifically, to address potential pollution from "inert" munitions constituents, e.g., heavy metals, 2,4,6-Trinitrotoluene (TNT), Volatile Organic Compounds (VOC), Royal Demolition Explosive (RDX), other toxic propellants, and their by-products, and spills, and leaks of other pollutants from being transported and bound into the ocean floor's benthic habitats where a myriad of aquatic species live and breed.

Given the first EIS was provided to the CNMI in 1997, it is disconcerting to see that the Navy has still not conducted studies to provide defensible evidence that explosives and other munitions and their constituents will NOT become bioavailable. The Navy has had over two decades to conduct meaningful research and yet nothing is provided herein, or cited directly.

Given the evidence of bioaccumulation of heavy metals in biota and invertebrates found at WWII dumps sites around the island of Saipan, substantiates our concern that further accumulation from ongoing exercises may result in cumulative impacts to aquatic organisms. Some of Gary Denton's studies (University of Guam, Water Environmental Research Institute) are cited herein:

Denton, G.R.W., et.al, (2016). *Impact of WWII dumpsites on Saipan (CNMI): heavy metal status of soils and sediments,* Environ Sci Pollut Res, DOI 10.1007/s11356-016-6603-7.

Denton, G.R.W., et.al, (2014). *Influence of Urban Runoff, Inappropriate Waste Disposal Practices and World War II on the Heavy Metal Status of Sediments in the Southern Half of Saipan Lagoon, Saipan, CNMI*. Mar. Pollut. Bull.

Denton, G.R.W., Starmer, J.A., Masga, R. (June 2013). *Environmental Impacts of FUDS and Brownfield Sties in Watershed on the Eastern Side of Saipan,* (CNMI). Phase 2: Impact on Aquatic Resources. *WERI Project Synopsis Report.*

Denton, G.R.W., Morrison, Bearden, Houk, Starmer, and Wood (2009). *Impact of a coastal dump in a tropical lagoon on trace metal concentrations in surrounding marine biota: A case study from Saipan, Commonwealth of the Northern Mariana Islands (CNMI).* Marine Pollution Bulletin 25 (2009) 424-455.

Denton, G.R.W., Bearden, B.G., Houk, P., Starmer J.A. & Wood H.R. (2008). *Heavy Metals in Biotic representatives from the Intertidal Zone and Nearshore Waters of Tanapag Lagoon, Saipan, Commonwealth of the Northern Mariana Islands (CNMI).* WERI Technical Report No. 123: 50 pp.

The Navy also states, "Metals released into the marine environment are not expected to exceed water quality standards in the CNMI coastal zone because corrosion and biological processes (e.g., colonization by marine organisms) would reduce exposure of military expended materials to seawater, decreasing the rate of leaching. Further, **leached metals would bind to sediments and other organic matter, thereby localizing the concentration to the site of deposition**."

The fact that heavy metals and other munition constituents may not be found in seawater at levels that would exceed the CNMI WQS is because of their octanol/water coefficient. In other words, these constituents instead partition into sediment and other organics. Heavy metal contaminants in the benthic habitat would be bioavailable to the fish and shellfish which results in bioaccumulation. Therein lies the issue. These pollutants would continue to be a source of contamination that may cause harm to aquatic marine life, and subsequently the people of the CNMI that rely heavily on subsistence fishing as significant part of their diet.

It is also the intent of the US Clean Water Act to protect our waters designated uses, which includes the protection and propagation of fish, shellfish and wildlife, and to ensure that fish in these waters are safe for human consumption.

A sediment study conducted in 2008-2009, off Saipan's west coast by Denton et.al., of University of Guam Water Environmental Research Institute found mercury "spikes" accompanied by increased CU, FE, MN and Zn enrichment, "which suggest they were remnant artifacts of the US invasion of Saipan in 1944. Mercury fulminate, for example, was the primary explosive used in primers and detonators of artillery shells and percussion caps of bullets during WWII (US Navy, 1947)."

In addition, this page also states that, "Some expended plastics from military readiness activities are unavoidable because they are used in ordnance or targets. Targets, however, would typically be recovered following training and testing activities. ***Chaff fibers are composed of nonreactive metals and glass, and would be dispersed by ocean currents as they float and slowly sink toward the bottom***. The fine, neutrally buoyant chaff streamers would act like particulates in the water, temporarily increasing the turbidity of the ocean's surface. The chaff fibers would quickly disperse, and turbidity readings would return to normal. Because activities would occur in areas outside of the CNMI coastal zone and the rapid settling and non-reactivity of materials not recovered after use, water quality standards in the CNMI coastal zone would not be exceeded."

However, the deposition of these nonrecoverable pollutants would contaminate the ocean bottom, benthic habitat, biota, and add to the growing volume of marine debris found in Pacific gyres, which have created the "Great Pacific Garbage Patch". The Department of the Navy is approaching these contaminants as being acceptable outcomes without explanation.

CNMI WQS stipulates that "all surface waters shall be free of substances attributable to domestic, industrial, or ***other controllable sources of pollutants and shall be capable of supporting desirable aquatic life*** and be suitable for recreation in and on the water." Waters are "subject to verification by monitoring as may be prescribed by the Administrator to assure freedom from any of the following conditions: ***.....(2) floating debris***, oil, grease, scum, or other ***floating materials..... (4)*** High temperatures; biocides; pathogenic organisms; ***toxic, corrosive, or other deleterious substances at levels or in combinations sufficient to be toxic or harmful to human health or aquatic life***, of in amounts sufficient to interfere with any beneficial use of the water." Detrimental responses include ***significant alterations in water biota***.

The presence of marine debris has been shown to be harmful to aquatic life in peer reviewed research papers from NOAA, US and European government agencies, and non-government agencies. The accumulation of military exercise contaminants in the habitat where fish and other aquatic life live, feed and breed are also of concern. The CNMI WQS states that, "all waters shall be free from toxic pollutants **in concentrations that are lethal to, or produce detrimental physiological responses in human, *plant or animal life***."

With this in mind, we continue with our concerns with statements made in the following section:

PUBLIC LAW NO. 3-47

Pages: 20 - 22

Adverse physiological responses in marine animals were marginally evaluated. To quote, "**Acoustic Stressors**. Pursuant to the MMPA***, acoustic sources may result in Level A and Level B harassment of certain marine mammals.*** The analysis completed by ***the Navy predicts no mortalities*** and therefore the Navy is not requesting an incidental take under the MMPA for mortality. Pursuant to the ESA, sonar and other transducers, weapons noise, vessel noise, air guns, and aircraft may affect certain ESA-listed marine mammals. herein."

A similar stance was taken with other stressors discussed in this section. Only mortality is considered, not morbidity that may further weaken marine animals causing a cumulative affect leading to latent mortality from chronic exposure to these and other climate related stressors.

The CNMI has experienced two Super Typhoons in the last five (5) years, and increasing marine water temperatures. These climate related stressors alone have led to marine animal morbidity and death, and wide spread coral reef damage. Stressing marine plants and animals further with acoustic, explosive, physical disturbance from sonar, vessel strikes or near misses, entanglement and ingestion stressors, is indefensible, as morbidity furthers their vulnerability to an avoidable early death.

Saipan, MP 96950

Re: *Comment on Federal Consistency Determination Request for Military Training and Testing (MITT) Within the Coastal Zone of the Commonwealth of the Northern Mariana Islands*

Dear Director Castro,

Thank you for this opportunity to comment on the Federal Consistency Determination (CD) request currently under consideration by the Bureau of Environmental and Coastal Quality's Division of Coastal Resources Management (DCRM), dated Dec. 19, 2019 and submitted to the Commonwealth of the Northern Mariana Islands (CNMI) Bureau of Military Affairs (BMA). As you know, ensuring consistency of significant federal actions with requirements put in place to protect our coastal resources is a policy matter of utmost importance to the CNMI. For the reasons outlined below, the 2019 CD submission is inadequate and in many aspects in disagreement with land management policies and mandates established by the CNMI Constitution and the Covenant, as well as key enforceable policies of the CNMI's Coastal Zone Management Program. As such, I encourage you to work with the Navy to ensure these concerns are addressed and that a sufficient CD request is submitted to you, with the Commonwealth Bureau of Military Affairs (CBMA) copied as is required, for your review and determination upon this proposal.

Procedural Issues

- **Streamlined submission supports local review**. The Navy's inclusion of the CBMA in their CD request is appreciated, however, the process outlined in **16 U.S.C. § 1456(c)(1)(C) and reflected** on the DCRM website and federal consistency guidance does clearly state that these requests should be provided to the "relevant State agency designated under section 1455(d)(6)" and therefore CDs should be addressed to the DCRM Director. As outlined in Executive Order 2019-09, CBMA is a clearing house and coordinating entity that functions as a custodian to support Department of Defense (DoD) related activities in the Commonwealth, and the Special Assistant acts as a liaison between DoD and CNMI Agencies. As such we believe that a proper CD submission would be addressed to the DCRM Director who reviews such determinations, in care of the CBMA Special Assistant. The CBMA Special Assistant has concurred with this assessment in discussions regarding this submission. We hope that a revised CD might be provided to your office to address the substantive deficiencies outlined here and ensure timely processing, as well as to support meaningful public notice and comment and participation opportunities moving forward.

- **References to obscure supporting documents complicates local review.** Documents referenced in CD should be included in the request itself. Although your DCRM staff have helpfully provided additional background information, the CD from DCRM on record for the MITT was dated January 20, 2015, we do not have a copy of the Navy's original documents. These materials are necessary to support meaningful review of this request, which relies heavily on this past correspondence. Therefore, it is

Page 1 of 8

requested that DoD provide this document and any other referenced supporting documents as links or digital files in a properly submitted CD request in advance of DCRM's final determination on this contention proposal.

- **Insufficient information is included in the Draft SEIS to support review at this time.** Data relied on in the SEIS is insufficient to assess likely impacts to coastal resources and as such, this CD request is not ripe for review. We encourage DCRM to request that the Navy treat the December 2019 as a draft and properly submit a revised CD request to you, the Director of the CNMI's Coastal Zone Program with the coordinating office of the BMA copied upon release of the updated draft or final SEIS. Where data gaps exist in terms of impacts to limited access, water quality, impacts to cetaceans and other marine life especially during spawning events, and mass wasting at FDM are not properly addressed, we hope DCRM can work with the Navy through this process to provide time bound conditions for execution of compliant activities as well as data sharing and coordination with local resource management agencies in CNMI.

Substantive Issues

- **Impacts to all CNMI lands and waters should be assessed for consistency.** Impacts to all CNMI land and coastal waters should be assessed for consistency with DCRM enforceable policies. The 2019 CD incorrectly excludes land-based activities proposed on FDM and Tinian from analysis based on the fact that "federally controlled lands are excluded from the coastal zone" (2019 CD, pg. 4). While CNMI does not dispute that the federal government has an interest in these lands, these lands have been "***made available to the Government of the United States by lease*** to enable it to carry out its defense responsibilities" and thus remain Commonwealth property which will revert to CNMI control when the leases terms expire (CNMI Covenant, Section 802, emphasis added). It is unclear on what basis the Navy states that these lands are not subject to federal consistency review, which should also include consideration of potential spillover effects to all CNMI-owned submerged lands and waters.

- **Details regarding activities and impacts are insufficient for review.** It is unclear from the description provided on page 2 of the 2019 CD what proposed activities would be occurring within three (3) nautical miles of the CNMI's shorelines. Thus, insufficient information has been provided to CNMI for DCRM to assess and determine whether the proposed MITT activities are consistent with applicable regulations as detailed further in discussion of application of specific enforceable policies below.

- **CD does not address direct, indirect, and cumulative impacts to lands and waters of the CNMI.** The CD incorrectly states that there are "no changes in land-based training proposal" (2019 CD, pg. 2). Assessment of activities in the 2019 Draft MITT Supplemental Environmental Impact Statement indicates that "[a]lternative 1 reflects a level of training and testing activities to be conducted at sea ***and on FDM***, with adjustments from the 2015 MITT Final EIS/OEIS that account for changes in the types and tempo of activities necessary to meet current and future military readiness requirements beyond 2020" and "Alternative 2 includes the same type of training and testing activities that would occur under Alternative 1. Alternative 2 also considers an increase in tempo of some training and testing activities, including additional Fleet exercises and associated unit-level activities, should unanticipated emergent world events require increased readiness levels" (2019 MITT Draft SEIS, Volume 1, pg. ES-5, emphasis added). In reviewing the "Summary of Impacts" table in the Draft Supplemental EIS/OEIS, additional details are provided indicating that:

  - Under Alternative 1, "more aircraft would fly over ***and land on FDM and more ordnance would be used on FDM***. The total increase, in terms of net explosive weight (NEW) under Alternative 1 would be less than 1 percent compared to ordnance use on FDM described in the 2015 MITT Final EIS/OEIS" and, "the number of training and testing activities under Alternative 2 would increase

CNMI Office of the Governor | Juan A. Sablan Memorial Building | Capitol Hill, Saipan
Caller Box 10007 | Saipan, MP 96950 | Telephone: (670) 237-2200 | Facsimile: (670) 664-2211 | www.gov.mp
Ralph DLG. Torres | CNMI Office of the Governor

over what is proposed for Alternative 1. However, this increase would be a slight change and would not appreciably change the potential for impacts over what is analyzed for Alternative 1" (Draft SEIS, pg. ES-18, emphasis added). The basis for this statement is unclear, as Table 3.0-19 of the DEIS, *Annual Number of Munitions Used on Farallon de Medinilla* shows greater than 1 percent increases in use explosive missiles (85 missiles authorized in 2015 Final EIS, 115 proposed under Alternatives 1 and 2), explosive grenades and mortars (600 authorized in 2015 Final EIS, 1,000 proposed under Alternatives 1 and 2), as well as increases in use of small-caliber rounds and medium caliber projectiles (see DEIS pg. 3-28). It also appears that annual in-water and in-air explosives munitions detailed in Tables 3.0-7 and 3.0-8 of the DEIS (pg. 3-22 – 23) will include increasing use of "E8", "E9", and "E10" explosives. It is unclear what portion of these munitions are proposed for testing activities in areas around FDM or in proximity to other CNMI lands and territorial waters, however, it appears that the proposed change is rather substantial for some explosive categories (e.g. bombs with net explosive weight between 60 – 500 pounds). The DEIS notes that "[a]s described in the 2015 MITT Final EIS/OEIS, physical disturbance and strike stressors can result from the Navy's proposed use of aircraft and aerial targets, vessels, in-water devices, military expended materials, seafloor devices, and, on the island of FDM, ground disturbance and wildfires" (DEIS, pg. 3-25). It is suggested that the actual proposed changes and likely impacts of these changes be meaningfully discussed in the updated DEIS and corresponding revised CD to ensure consistency with enforceable policies in sea and on land.

- **As currently submitted, the proposed action is not consistent with DCRM Enforceable Policies.** Under the Coastal Zone Management Act (CZMA) of 1972, 16 USC § § 1451-1465, § 1456(c)(1), and Federal Consistency regulations, 15 CFR § § 930.30-930.46, Federal agency activities with reasonably foreseeable effects on the State's coastal zone must be consistent to the maximum extent practicable with the enforceable policies of the States' federally approved CZMA programs. Under 15 CFR §930.32(a)(1), the standard for "consistent to the maximum extent practicable" means fully consistent with the enforceable policies of the CNMI's management programs unless full consistency is prohibited by existing law applicable to the Federal agency. Thus, the Navy must show how existing law prohibits full consistency with the CNMI's Coastal Management Program. However, the Navy has not provided any description of any statutory provisions, legislative history, or other legal authority which limits the Navy's discretion to be fully consistent with the enforceable policies of CNMI's management program. Furthermore, 15 CFR §930.32(a)(2) details that 16 USC § 1456(e), "construction with other laws", or "Section 307(e) of the Act does not relieve Federal agencies of the consistency requirements under the Act. The Act was intended to cause substantive changes in Federal agency decision making within the context of the discretionary powers residing in such agencies. Accordingly, ***whenever legally permissible, Federal agencies shall consider the enforceable policies of management programs as requirements to be adhered to in addition to existing Federal agency statutory mandates***. If a Federal agency asserts that full consistency with the management program is prohibited, it shall clearly describe, in writing, to the State agency the statutory provisions, legislative history, or other legal authority which limits the Federal agency's discretion to be fully consistent with the enforceable policies of the management program" (emphasis added). Accordingly, for the reasons cited below, the proposed MITT is not fully consistent with enforceable policies of the CNMI's approved CZMA program:

  - **Full consistency with local permitting required**. The 2019 CD incorrectly states that General Provisions (15-10-020, 15-10-025) and Standards for CRM Permit Issuance (15-10-301, 305, 315, 320, 325, 335, 340, 345), Major Siting Standards (15-10-501, 505), and CRM Permit Conditions (15-10-610) and numerous policy elements of Public Law 3-47 do not apply. If the Navy feels that certain sections do not apply, details should be provided to further frame discussion regarding the applicability and extent of the enforceable policies for the CNMI's CZMP. That being said, these provisions have been applied to CD review and should continue to be applied to ensure consistency with CNMI's enforceable polices. Concerns regarding specific subsections are outlined further

CNMI Office of the Governor | Juan A. Sablan Memorial Building | Capitol Hill, Saipan
Caller Box 10007 | Saipan, MP 96950 | Telephone: (670) 237-2200 | Facsimile: (670) 664-2211 | www.gov.mp
Ralph DLG. Torres | CNMI Office of the Governor

below. However, it is a misconstruction of the intent and letter of the CZMA to state that mandatory conditions and management standards of the CZMA are not applicable. Rather, proposed activities must comply with substantive local permitting requirements as they are incorporated through the DCRM Coastal Management Program. Given the extensive mitigation that should be implemented to address impacts of proposed increases in the activities outlined in Table 1 of the 2019 CD, the Navy should anticipate coordinating with local regulatory agencies to implement required clean up activities. Obtaining local permits, although it may not be required for all potential survey, clearing, and clean-up activities, would demonstrate the Navy's commitment to complying with local requirements and coordinating with our local agencies. This is a best practice that other federal agencies engage in and we encourage you to ask the Navy and other DoD branches to extend this courtesy to our regulatory and resource management partners. At minimum, the 2015 Federal Consistency Determination from DCRM conditioned coordination with local authorities which, to this day, has been insufficient and in some cases as resulted in avoidable losses of or damage to important CNMI assets that DoD has yet to remedy.

- **Application of CD analysis to all relevant enforceable policies is necessary.** Similar to the concerns raised in the Oct. 2014 DCRM response to the Sept. 2014 CD request, it appears that numerous elements of the currently proposed revised and expanded MITT are not consistent with DCRM's enforceable policies. These include:

  - Assessment of impacts for compliance with general standards (15-10-305), Areas of Particular Concern (15-10-315, 325, 335, 340) and specific criteria for major sitings (15-10-505).

    As stated in the Office of the Governor's comments on the MITT DEIS, there has been insufficient analysis of direct, indirect, and cumulative impacts of MITT activities. This analysis should include all reasonably foreseeable and related activities including but not limited to activities described in the Guam and CNMI Military Relocation FEIS/OEIS, Divert Activities and Exercises, the MITT expansion, and upcoming CNMI Joint Military Training DEIS/OEIS. If implemented these activities will undoubtedly have cumulative effects on CNMI's coastal resources. Thus far, insufficient information has been provided in supporting documents and in this CD request for CNMI assess consistency with this provision. As outlined in 15-10-305, criteria for development, which is defined to include activities relevant to the MITT "discharge or disposal of … any gaseous, liquid, solid, or thermal waste" (15-10-020(z)(2)); a "change in the density or intensity of use of land" (15-10-020(z)(4)); a "change in the intensity of use of water, the ecology related thereto, or the access thereto" (15-10-020(z)(5)); or the "removal of a significant amount of vegetation, whether native or non-native" (15-10-020(z)(7)), development criteria must include consideration of cumulative impacts, compatibility, alternatives, conservation, compliance with local and Federal laws, consistency with the CNMI's Constitutional right to a clean and healthful environment, effects on existing public services, adequate public access, setbacks, management measures for control of nonpoint source pollution, and buffers for environmentally sensitive areas (15-10-305). If the Navy feels that consistency with these standards is not legally permissible, they should detail their rationale for this position in their CD request – otherwise the applicable regulations appear to direct that these policies be considered and adhered to. Reasonably foreseeable impacts to Areas of Particular Concern should also be assessed for consistency, especially in terms of potential direct and spillover effects to lagoon and reefs (15-10-315), coral reefs (15-10-325), shorelines (15-10-335) and ports (15-10-345), categories which the CD summarily said were not applicable due to unnecessarily narrow interpretation of these areas and their management standards. Similarly, "major siting" is defined as "any proposed project which has the potential to directly and significantly impact coastal resources" which includes "[p]roposed projects with potential for significant adverse effects on submerged lands, groundwater recharge areas,

CNMI Office of the Governor | Juan A. Sablan Memorial Building | Capitol Hill, Saipan
Caller Box 10007 | Saipan, MP 96950 | Telephone: (670) 237-2200 | Facsimile: (670) 664-2211 | www.gov.mp
Ralph DLG. Torres | CNMI Office of the Governor

cultural areas, historic or archeological sites and properties, designated conservation and pristine areas, or uninhabited islands, sparsely populated islands, mangroves, reefs, wetlands, beaches and lakes, areas of scientific interest, recreational areas, limestone, volcanic and cocos forest, and endangered or threatened species or marine mammal habitats" (15-10-020(uu)(4)). Given that this project clearly qualifies as a major siting, consistency with major siting standards of 15-10-505 should also be assessed.

- **Meaningful analysis of data and standards of enforceable policies is necessary.** In addition to lacking analysis noted above, as outlined herein, the CD analysis is currently inadequate in terms of assessment of impacts and analysis and application of enforceable policies in regards to discussion on water quality, Public Law 3-47 Policy Elements 4, 10, 11, 12, 13, 15, 16, 17, and 21.

  - Assessment of impacts to water quality. The CD states that "military readiness activities that generate stressors to water quality do not occur in the water use areas; rather, they occur outside of the CNMI coastal zone, and are analyzed in the context of their potential to induce reasonably foreseeable effects into Class "AA" or Class "A" water use areas." It goes on to restate conclusory statements that no effects are anticipated from explosives and explosive byproducts (Section 3.1.3.1), metals (Section 3.1.3.2), and other materials (Section 3.1.3.4) based on the analysis that activities would "occur in areas outside of the CNMI coastal zone" and in "rapid settling and non-reactivity of materials not recovered after use". Data has not been provided to confirm baseline water quality in areas of proposed activities or to substantiate these statements. This is especially disconcerting in regards to turbidity and total suspended solids where health and habitat protective standards aim to ensure that "[c]oncentrations of suspended matter at any point shall not be increased from ambient conditions at any time, and should not exceed 5 mg/l except when due to natural conditions" (for TSS) and "[t]urbidity at any point, as measured by NTU, shall not exceed 0.5 NTU over ambient conditions except when due to natural conditions." Additionally, the standard for all CNMI waters is that they "shall be free from toxic pollutants in concentrations that are lethal to, or that produce detrimental physiological responses in human, plant, or animal life. Detrimental responses include, but are not limited to: decreased growth rate and decreased reproductive success of resident or indicator species; or significant alterations in population, community ecology, or receiving water biota." Insufficient data has been provided to demonstrate that proposed increasing uses of weapons that will deposit explosives and explosive byproducts, metals, and other materials into CNMI waters will not violate this standard.

  - Policy Element 4 – "Plan for and manage any use or activity with the potential for causing a direct and significant impact on coastal resources. Significant adverse impacts shall be mitigated to the extent practicable." The Coastal Zone Management Act broadly defines the environment. Instead of considering impacts of increased activities to the people of the CNMI and the coastal resources that comprise our home, the CD narrowly discusses potential impacts to marine mammals, coral, and fishes in water and does not reassess impacts of land-based activities on Saipan, Tinian, and Rota or FDM, stating that no changes in these activities are proposed. As previously mentioned, FDM activities appear to be significantly increasing, and mitigation measures proposed by DCRM to ensure consistency with land-based operations in the 2015 MITT do not appear to have been implemented regularly – particularly as they pertain to early coordination and data sharing with CNMI. It is unclear why the Navy states that mitigation measures are outside of the scope of this SEIS/OEIS (CD enclosure pg. 23), especially given the fact that the 2014 CD correspondence from DCRM noted that "[i]n order to comply with the enforceable polices of the CNMI, further measures are needed to protect the wildlife and habitats of the CNMI". Similarly, in this CD request like the 2014 submission, the basis for finding that the MITT is consistent to the maximum extent practicable has not

CNMI Office of the Governor | Juan A. Sablan Memorial Building | Capitol Hill, Saipan
Caller Box 10007 | Saipan, MP 96950 | Telephone: (670) 237-2200 | Facsimile: (670) 664-2211 | www.gov.mp
Ralph DLG. Torres | CNMI Office of the Governor

been established. The Navy must show how its proposed actions are fully consistent by providing data, not speculative conclusions such as that potential effects to endangered species will be addressed through pending biological opinions. As also noted previously, the statement that the "Navy's Proposed Action provides special protection to coastal resources and mitigates adverse impacts" is inadequate to demonstrate consistency as the SEIS/OEIS does not actually commit to mitigation measures or timelines for implementation of mitigation, making these assurances rather hollow and unenforceable. If the Navy plans to rely on the suite of mitigation options discussed in the Draft SEIS/OEIS to demonstrate compliance with CNMI's enforceable policies including the requirement of mitigation of adverse impacts, meaningful and enforceable commitments and timelines for implementation should be developed as part of this CD correspondence.

- Policy Element 10 – "Maintain or improve coastal water quality through control of erosion, sedimentation, runoff, siltation, sewage and other discharges." It is unclear how the Navy is able to state that proposed activities will not result in siltation, runoff, and other discharges given the use of munitions on land at FDM and in the CNMI's coastal waters. Assessment of this policy element and supporting regulations is inadequate and this analysis should be revised to support DCRM's review of this CD request.

- Policy Elements 11 and 12 – Impacts to cultural resources. Although Section 106 consultations are ongoing to support the reissuance of the expired Programmatic Agreement, the analysis of impacts to cultural resources referenced in Section 3.11 of the draft SEIS/OEIS does not include sufficient data to make any determination regarding likely significant impacts to cultural resources within CNMI waters and on FDM. Absence of evidence is not evidence of absence and the DoD has an obligation to implement reasonable assessment of resources that are likely to be impacted by MITT activities. Lacking that data, there is therefore no basis for the Navy's conclusion that this proposed action is consistent with these policy elements. Data gaps should be remedied to ensure consistency with these policies and the CNMI's significant and compelling interest to protect and preserve our cultural resources.

- Policy Element 13 – "Require compliance with all local air and water quality laws and regulations and any applicable federal air and water quality standards." Data must be provided to support the conclusory statements that air emissions will be minimal on Saipan and Rota and will be "intermittent and short term, resulting in minimal impact on the air quality of Tinian". Models are available to assess these activities for compliance with local and federal air quality standards and should be included for review in this submission. Comments regarding water quality standards are incorporated by reference here.

- Policy Elements 15 and 16 – Management of marine resources and consistency with other policies. As noted in the response to Policy Element 4, the Navy's analysis of impacts to coastal resources is overly narrow and does not meaningfully address impacts to the human environment. This is especially true regarding impacts to the integrity of our reefs and wildlife habitat (Policy 15) and the management and development of our local subsistence, sport, and commercial fisheries (Policy 16). The draft SEIS/OEIS contains insufficient assessment of the potential impacts to these resources and the "analysis" under Policy Element 4 does not address potential impacts to human uses such as fishing and traditional access to important fishing areas. Thus, it is unclear how the Navy can conclude their proposed actions are consistent when analysis is completely lacking. An updated CD should address this gap, preferably through a revised SEIS that provides meaningful analysis of impacts to these important coastal resources.

CNMI Office of the Governor | Juan A. Sablan Memorial Building | Capitol Hill, Saipan
Caller Box 10007 | Saipan, MP 96950 | Telephone: (670) 237-2200 | Facsimile: (670) 664-2211 | www.gov.mp
Ralph DLG. Torres | CNMI Office of the Governor

- Policy Element 17 – "Protect all coastal resources, particularly sand, coral and fish from taking beyond sustainable levels and in the case of marine mammals and any species on the Commonwealth endangered species list, from any taking whatsoever." The Navy explains that "the Proposed Action has the potential to take marine mammals and species on the Commonwealth endangered species list" and that "[a]ny take occurring as a result of the Proposed Action would be incidental to, and not the purpose of, the Navy's otherwise lawful training and testing activities" and notes that protective measures intended to avoid and minimize the "take" of endangered species will be updated as appropriate upon completion of the Section 7 consultation. As noted previously, past promises of mitigation and monitoring have not been executed, or, if they have been, have not been shared with the CNMI, therefore, it is encouraged that any monitoring and mitigation agreements that are the basis for a consistency determination include timebound deliverables so that consistency can be demonstrated.

- Policy Element 21 – "Encourage the preservation of traditional rights of public access to and along the shorelines consistent with the rights of private property owners." Contrary to the Navy's statement that the "MITT Draft Supplemental EIS/OEIS does not propose any change to the public access normally allowed on federally leased lands including FDM, which would remain restricted for security and safety reasons" and that the "MITT Draft Supplemental EIS/OEIS does not propose a change to the ocean areas currently used by both the Navy and the public", increases in the intensity and use of CNMI lands and waters is more likely than not to have significant impacts to public access of shorelines and traditional fishing areas. Already, three nautical miles (nm) surrounding the abundant fishery surrounding FDM is periodically restricted and this SEIS proposes to extend that "danger zone" to 12 nm and increase the frequency of restricted use in this area. These restrictions can have direct and significant impacts to boaters and the fishing community by increasing travel time and forcing seagoing vessels to travel well out of their traditional navigation routes. Similarly, periodic exercises on Tinian significantly restrict community access to forests and shorelines that have been traditionally used for subsistence and commercial activities. The frequency and timing of these restrictions should be discussed further with the CNMI in order to maximize access for users of these ocean resources while ensuring the Navy can meet its training objectives. Given that assessment of impacts and commitment to reasonable mitigation measures are lacking in the SEIS/OEIS, meaningful commitments should be articulated in supplemental analysis in a revised CD in order to ensure consistency with this enforceable policy.

- **Enforceable commitments to proposed offsets and mitigations needed.** DCRM's October 2014 response to the September, 2014 CD (letter 5090 Ser N465/0926) outlines numerous mitigation measures that the Navy would need to implement to ensure consistency with CNMI enforceable policies. These include collection of baseline data on impacts to essential fish habitat areas, assessment of impacts to endangered bird, marine mammals, and sea turtle populations, water quality monitoring to ensure water quality stays within CNMI standards, and suggests addressing mass wasting concerns at Farallon de Medinilla as well as the removal of Rota for any activities. It does not appear these data gaps were ever addressed, or, if they were, that data was never shared with the CNMI. Additionally, in recent MITT discussions CNMI was informed that the Navy is unable to commit to mitigation actions or timelines due to lack of advance appropriations for these activities. The result of this procedural issue is ongoing activities with insufficient mitigation measures. Avoidance and minimization of impacts should be the first step in the scoping process, and mitigation actions that are agreed to should be implemented in a timely manner. As it stands, it appears that the majority of mitigation measures outlined in the 2014 CD correspondence have still not been implemented. Without these measures, the 2015 – 2020 MITT activities do not reflect good faith efforts to comply with conditions from the last CD process, let alone establish a record

Ralph DLG. Torres | CNMI Office of the Governor

of performance that can be relied upon as a basis for ongoing and significantly expanded activities on land and at sea. Direct, indirect, and cumulative impacts must be meaningfully assessed in order to be avoided, minimized, and then actually mitigated. We believe an updated CD and revised draft SEIS will be necessary to address the substantial data gaps identified here and that time bound commitments for key mitigation measures will be needed to support substantive compliance with the federal consistency review process.

For the reasons outlined herein, our office encourages DCRM to work with the Navy to resolve the procedural and substantive concerns raised by the December 2019 CD. We strongly encourage a supplemental submission be considered when data gaps identified in the draft SEIS are resolved.

Thank you for your consideration of these concerns and your ongoing support of this process.

Sincerely,

GILBERT J. BIRNBRICH

C.2.3 NAVY CONSISTENCY DETERMINATION LETTER – GOVERNMENT OF GUAM

DEPARTMENT OF THE NAVY
COMMANDER
UNITED STATES PACIFIC FLEET
250 MAKALAPA DRIVE
PEARL HARBOR, HAWAII 96860-3131

IN REPLY REFER TO:
5090
Ser N465/1462
December 09, 2019

Mr. Tyrone J. Taitano
Director
Bureau of Statistics and Plans
P.O. Box 2950
Hagatna, Guam 96932

Dear Mr. Taitano:

SUBJECT: CONSISTENCY DETERMINATION FOR MILITARY TRAINING AND TESTING WITHIN THE GUAM COASTAL ZONE

In accordance with the Federal Coastal Zone Management Act (CZMA) and 15 C.F.R. Part 930, the U.S. Navy submits the enclosed Federal Consistency Determination (CD) for proposed activities in the Mariana Islands Training and Testing (MITT) Study Area that have reasonably foreseeable coastal effects on the coastal use or resources of Guam.

Based on the enclosed consistency determination and the activities and analysis contained in the enclosed Draft Supplemental Environmental Impact Statement/Overseas Impact Statement (DSEIS/OEIS), the Navy finds that the proposed military training and testing activities presented in Alternative 2 are consistent to the maximum extent practicable with the enforceable policies of the Guam Coastal Management Program.

We look forward to your timely review of and concurrence with the Navy's determination. If you have any questions, please contact Mr. John Van Name at (808) 471-1714 or john.vanname@navy.mil or Ms. Suzanne Smith at (808) 471-4696 or suzanne.smith3@navy.mil.

Sincerely,

DANIEL McNAIR
Director, Fleet Environmental Readiness
By direction of the Commander

RE: Coastal Zone Management Act (CZMA) Federal Consistency Review for Department of the Navy's proposed activities in Mariana Islands Training and Testing (MITT) Study Area *(GCMP FC No. 2020-0001)*

Hafa adai! The Guam Coastal Management Program of the Bureau of Statistics and Plans (Bureau) has completed its review of the Federal Consistency Determination by the Department of the Navy received on January 8, 2020. The Department of the Navy ("the federal agency") has submitted its consistency determination relative to its proposed activities in Mariana Islands Training and Testing (MITT) Study Area.

The Bureau coordinated this review with partnering agencies, provided Public Notice, and received comments from Senator Sabina F. Perez, the Guam Environmental Protection Agency (GEPA), the Guam Waterworks Authority, the Department of Agriculture, and the Department of Parks and Recreation. Furthermore, the Bureau hereby concurs with the federal agency's determination that the proposal is consistent with the enforceable policies of the Bureau's Guam Coastal Management Program (GCMP) based upon the following comments and conditions:

Resource Policy. Conservation of Natural Resources—Overall Policy. *The value of Guam's natural resources as recreational areas, critical marine and wildlife habitats, the major source of drinking water, and the foundation of the island's economy shall be protected through policies and programs affecting such resources.*

According to the Draft Supplemental EIS/OEIS, the proposed activity is expected to result in the equivalent of at least 151,918 metric tons of carbon dioxide emissions per year (which would total 759,590 metric tons of carbon dioxide equivalent emissions over 5 years). As climate change is expected to result in sea level rises, potentially more damaging tropical storms, a reduction in the recharge rate of the Northern Guam Lens Aquifer, and other environmental and societal

Doc. No. 35GL-20-1874.*

impacts, substantial increases in greenhouse gas emissions provide impacts in several of the different elements of this policy for the conservation of natural resources.

Pursuant to this resource policy, the federal agency is hereby advised to consider mitigation strategies to reduce the net carbon dioxide equivalent emissions of the proposed action, to the maximum extent practicable, which could include methods of reducing carbon dioxide equivalent emissions or methods of capturing carbon dioxide equivalent emissions through natural or other processes.

Resource Policy 1. Air Quality. *All activities and uses shall comply with all local air pollution regulations and all appropriate Federal air quality standards in order to ensure the maintenance of Guam's relatively high air quality.*

The federal agency's proposed actions are estimated to increase annual emissions from criteria pollutants within the study area of 77 tons per year for nitrogen oxide and 78 tons per year for carbon monoxide under Alternative 1 or 78 tons per year for nitrogen oxide and 79 tons per year for carbon monoxide under Alternative 2, both compared to baseline emissions. These are under the 250 ton per year prevention of significant deterioration (PSD) thresholds. Other criteria pollutants have significantly lower additional output under both alternatives. The federal agency further finds that the quantities of hazardous pollutants released would result in negligible quantities of hazardous air pollutants in localized areas not publicly accessible. According to the Draft Supplemental EIS/OEIS, the proposed activity is expected to result in the equivalent of at least 151,918 metric tons of carbon dioxide emissions per year (which would total 759,590 metric tons of carbon dioxide equivalent emissions over 5 years).

The conclusion based upon the detailed stressor analysis in the Draft Supplemental EIS/OEIS that air pollution is minimal, intermittent and short-term does not adequately address cumulative impacts of repeated exposure of the population to criteria air or hazardous pollutants and the potential health impacts. Moreover, the analysis does not adequately evaluate cascading and cumulative impacts of the deposition of air pollutants on land, water, terrestrial and aquatic organisms and the ecosystem.

Pursuant to Resource Policy 1, Air Quality, the federal agency shall, to the maximum extent practicable:

(1) be advised to establish an empirical baseline for the health of the population which are in or near the most likely areas to experience effects from repeated exposure to air pollution due to the proposed activities in or near the coastal zone and conduct occasional monitoring of the health of the population within the likely affected areas. If findings indicate significant deterioration of the health of the most likely affected populations, the federal agency should coordinate its response with local agencies.

(2) be advised to establish an empirical baseline for the health of terrestrial and aquatic species which are in or near the most likely areas to

experience effects from repeated exposure to air pollution due to the proposed activities in or near the coastal zone and conduct occasional monitoring of the health of such species within the likely affected areas. If findings indicate significant deterioration of the health of terrestrial or aquatic species, the federal agency should coordinate its response with local agencies.

Resource Policy 2. Water Quality. *Safe drinking water shall be assured and aquatic recreation sites shall be protected through the regulation of uses and discharges that pose a pollution threat to Guam's waters, particularly in estuarine, reef and aquifer areas.*

The federal agency stated in its consistency determination that activities including the use of explosives and explosion byproducts, military materials with metal components, and chemicals other than explosives would occur in federally owned submerged land, or more than 3 NM offshore, thus outside of Guam's coastal zone. Impacted sediments and water quality would only be immediately adjacent to the munitions, hence activities would have no significant effect on sediments and water quality within Guam's coastal zone. Furthermore, the Navy concluded that neither state nor federal standards or guidelines would be violated by the chemical, physical, or biological changes in sediment or water quality measurable at the detonation site.

The federal agency should continue to conduct water quality impact analysis to determine that explosives and explosive byproducts, metals and other materials expended during training and testing described in the MITT Final Supplemental EIS/OEIS would not exceed regulatory thresholds and guidelines [Sediment characterization methods in Guam Water Quality Standards (2017) and USEPA established criteria for concentrations of explosives, explosive byproducts and metal in saltwater] established for measuring impacts on sediment and water quality.

GEPA has expressed its concern that there was no discussion of marine debris cleanup as a result of the MITT activities once completed. The MITT Final EIS/OES 2015 (p. 3.1-55) discusses other materials as follows: Other military expended materials include plastics, marine markers, flares, and chaff. Some expended plastics from training and testing activities are unavoidable because they are used in ordnance or targets. (Although plastics are resistant to degradation, they do gradually break down into smaller particles because of sunlight and mechanical wear [Law et al. 2010]. Thompson et al, [2004] found that microscopic particles were common in marine sediments at 18 beaches around the United Kingdom. They noted that such particles were ingested by small filter and deposit feeders, with unknown effects.) Targets, however, would typically be recovered following training and testing activities. Chaff fibers are composed of nonreactive metals and glass, and would be dispersed by ocean currents as they float and slowly sink toward the bottom. The fine, neutrally buoyant chaff streamers would act like particulates in water, temporarily increasing the turbidity of the ocean's surface. The chaff fibers could quickly disperse, and turbidity readings would return to normal.

Section 2 of the 2019 MITT Draft Supplemental EIS/OEIS describes the annual Proposed Action and Alternatives. However, the MITT has a five-year term. Cumulative impacts of the Range activities, in terms of the amount of Ordnance (or other expended items, if any) should be considered over five years, on-going versus Alternative 1 and Alternative 2. Tables 2.5-1 and 2.5-2 compare the proposed SEIS/OEIS action alternatives with on-going training and testing activities. Each table describes the activities in terms of the activity name and where in the Study Area the federal agency proposes to conduct it. The next two columns show the annual occurrence and ordnance or other expended items (if any) involved in the activity as is currently ongoing (under the heading "2015 MITT EIS/OEIS Ongoing Activities"). The final two pairs of columns present the same information (annual occurrence and ordnance/items) as the activities are analyzed in the 2019 Supplemental EIS/OEIS for Alternative 1 and Alternative 2, respectively. As an example, page 2-33 has a Surface Warfare range activity located 12 NM from land. Ongoing activities list 242 events per year (1,210 over 5 years) and 48,040 small caliber rounds annually (or 240,200 small caliber rounds over 5 years) The number of rounds increases in the Alternative 1 & 2 scenarios by 128,400 small caliber rounds annually or 642,000 small caliber rounds over 5 years. The narrative in Section 4.4.1, Sediment and Water Quality, concludes that proposed changes in training and testing activities under Alternative 1 or Alternative 2 would be negligible.

In the 2019 Supplemental MITT, Section 3.1.2.3 Other Materials explains that detonations, explosions, and other activities may result in dispersal of glass, carbon fibers, plastics, rubber, steel, iron, concrete, etc. There is no discussion of any effort to clean up the marine debris as a result of the proposed activities.

In the 2019 Supplemental MITT, Section 5.1.2.2.1.1 Adaptive Management states that the adaptive management process is to help the federal agency have better knowledge of ecological systems. The process involves technical review meetings and ongoing discussions between the Department of the Navy, National Marine Fisheries Service, the Marine Mammal Commission, and other experts in the scientific community.

Pursuant to Resource Policy 2, Water Quality, the federal agency shall, to the maximum extent practicable:

(1) be advised to provide a map delineating the proposed Agat Bay and Piti underwater Mine Warfare detonation sites to the Bureau and Guam Environmental Protection Agency to clarify that those sites are outside of Guam's coastal zone, as represented.

(2) continue to conduct water quality impact analysis to determine that explosives and explosive byproducts, metals and other materials expended during training and testing described in the MITT Final Supplemental EIS/OEIS would not exceed regulatory thresholds and guidelines [Sediment characterization methods in Guam Water Quality Standards (2017) and USEPA established criteria for concentrations of explosives, explosive byproducts and metal in saltwater] established for measuring impacts on sediment and water quality.

(3) be advised to provide information on planned cleanup activities, if any, for marine debris to the Bureau and GEPA.
(4) be advised to include local stakeholders or local natural resource managers such as GEPA, Guam Department of Agriculture, and the Bureau.

Resource Policy 3. Fragile Areas. *Development in the following types of fragile areas shall be regulated to protect their unique character.*

- *historical and archeological sites*
- *wildlife habitats*
- *pristine marine and terrestrial communities*

As stated in the 2019 MITT Draft Supplemental EIS/OEIS, activities involving vessels and in-water devices are not intended to contact the seafloor. This would include amphibious and expeditionary events such as Amphibious Assaults, Amphibious Raids, Personnel, Insertion/Extraction/ and Underwater Surveys, which are proposed to continue in this SEIS/OEIS. As is current practice, coral and other hard bottom habitats would continue to be avoided to the greatest extent practical under the Proposed Action (see Section 2.3.3, Standard Operating Procedures and Chapter 5 – Mitigation). However, combat swimmers and Marines may be required to walk through nearshore areas during these activities. For example, as the boat approaches a beach, Marines may be required to exit the boat, stand up, and walk through the shallow water habitats. GEPA noted that in previous assaults on Guam, it has been observed that physical damages, including corals crushed or turned over, from these training activities occurred. As discussed in Section 5.4.1 (Mitigation Areas for Seafloor Resources), the Navy will implement mitigation to avoid or reduce impacts from precision anchoring and military expended materials on seafloor resources in mitigation areas throughout the Study Area.

Portions of the study area include marine communities. The Guam Department of Agriculture's Division of Aquatic and Wildlife Resources (DAWR) is the responsible local agency with the responsibility for protecting aquatic and wildlife resources, including marine preserves and sensitive areas.

Pursuant to Resource Policy 3, Fragile Areas, the federal agency shall, to the maximum extent practicable:

(1) be advised that any and all construction that is related to the proposed activities may be subject to permitting by GEPA and such permitted activity shall meet all relevant requirements of GEPA regulations and permitting by U.S. Army Corps of Engineers and subject to further federal consistency review.
(2) be advised to instruct swimmers and Marines to exercise caution when interacting with sensitive marine environments.
(3) be advised to communicate with DAWR in regards to planned activities involving sensitive areas.
(4) be advised to establish a coral damage response plan, which includes triage, restoration, and subsequent monitoring.

Resource Policy 4. Living Marine Resources. *All living resources within the territorial waters of Guam, particularly corals and fish, shall be protected from over harvesting and, in the case of marine mammals, from any taking whatsoever.*

GEPA finds that the proposed federal agency activities are consistent with the GCMP resource policies for marine invertebrates. Benthic invertebrates of the reef crest or flat, such as crabs, clams, and polychaete worms, within the disturbed area could be displaced, injured, or killed during amphibious operations. GEPA notes that the federal agency notifies local regulatory agencies of upcoming underwater Mine Detonation activities within Outer Apra Harbor and Agat Bay. Neither the public nor the regulatory agencies receive any form of after-action reporting on the outcome of these activities, specifically if any environmental damages occurred. There is not a current mechanism to evaluate whether the activities, quantities, and reported impacts met or exceeded the anticipated levels.

The Department of Agriculture finds that the presence of ESA-listed sperm whales is well-documented within 3-5 NM offshore in the Agat area. Recently there have been multiple instances of whale strandings, raising the concern that additional explosive impacts or sonar activities may result in an intensification of similar occurrences. Increased boat activity greatly increases the potential for boat strike of sperm whales. Navy lookouts undergo extensive training in order to qualify as a watch stander. The effectiveness of watch standers should be evaluated.

The Department of Agriculture is concerned about the impact of landing craft exercises on the dolphins that reside in Agat Bay. The federal agency has contended that there are unavoidable impacts and recognizes the common occurrence of spinner dolphins within Agat Bay and developed mitigation measures in consultation with the National Marine Fisheries Service under provisions of the Marine Mammal Protection Act. Beachmasters are shore-based observers with binoculars whose sole purpose is to ensure the safety of craft including avoidance of marine and terrestrial animals. Beachmasters are to work with environmental monitors and natural resource managers. The effectiveness of beachmasters should be evaluated.

While there is discussion of metals which will be introduced into the natural aquatic environment as a result of activities as well as bioaccumulation of pollutants in aquatic species, the possibility of biomagnification is not introduced into the discussion of potential impacts. Bioaccumulation is the accumulation of toxic chemicals in the tissues of an organism, while biomagnification is the increasing concentration of toxic chemicals for animals which are higher on the "food chain." This tends to mean that the highest concentrations of toxic chemicals which are capable of bioaccumulation may occur in aquatic animals that are apex predators. For this reason, one may expect that where bioaccumulation occurs that higher concentrations might be found in predatory fish such as mahi, various species of tuna, etc.

Pursuant to Resource Policy 4, Living Marine Resources, the federal agency shall, to the maximum extent practicable:

(1) be advised to provide some form of report outlining Mine Detonation activities and highlighting any issues regarding water quality, fish kills, protected species sightings, and marine debris to the public and/or local regulatory agencies.

(2) be advised to establish a standard operating procedure to resume, at least biannually, pre-coordination meetings on Mine Detonation activities with regulatory agencies.

(3) be advised to produce an annual report summarizing activities identified in the MITT to indicate whether activities and quantities reported in the MITT are met or exceeded and reporting on environmental impacts of such activities.

(4) refrain from taking any non-pelagic fishes within the Piti Marine Preserve Area.

(5) be advised to clarify and analyze the potential effects to marine animals and habitats from underwater demolition, including habitat mapping in a more detailed manner, identification of the cetacean species that utilize the proposed area, and include impacts to sea turtles.

(6) not engage in any takings of endangered species.

(7) be advised to evaluate the effectiveness of watch standers and beachmasters in their ability to detect marine mammals, such as sperm whales.

(8) be advised to investigate whether there is a connection between military training activities conducted in or near Guam and whale strandings. If there is found to be a likely connection between training and whale strandings, then the federal agency is advised to adjust its standard operating procedures to reduce the likelihood of continued adverse impacts to whales in the waters around Guam.

(9) be advised to establish an empirical baseline for the health of aquatic species for which biomagnification cause higher concentrations of toxic chemicals, especially those which are commonly used for fishing purposes. If findings indicate significant increases in toxic chemicals in the species of aquatic species, the federal agency should coordinate its response with local agencies.

Resource Policy 7. Public Access. *The public's right of unrestricted access shall be ensured to all non-federally owned beach areas and all territorial recreation areas, parks, scenic overlooks, designated conservation areas and their public lands; and agreements shall be encouraged with the owners of private and federal property for the provision of releasable access to and use of resources of public nature located on such land.*

Previous proposed military activities have indicated the closure of fishing areas such as Ritidian and Pati Point. Further restrictions on access to fishing areas within territorial waters, whether by actions inside or outside of the coastal zone, due to training activities within territorial waters must be mitigated. Other boaters, including divers and other recreational users frequent many areas within the MITT study area. There is no clear indication of how extensive closures will be.

Access to reefs and seashore areas can sometimes be accomplished merely by passage within the coastal zone, but sometimes passage over federally owned submerged lands, including surface danger zones, may be required due to the freeflowing nature of the coastal marine environment and the impracticality of passage outside of the 3 or more NM contour, as the case may be, in order to access territorial waters for the purpose or recreation, fishing, or for other reasons.

Pursuant to Resource Policy 7, Public Access, the federal agency shall, to the maximum extent practicable:

(1) clarify the period lengths of time for which closure of access to territorial waters may occur and to propose mitigation to compensate for loss of access.
(2) establish standard operating procedures that will avoid, where possible, or minimize, where unavoidable, disruption of public access to reefs and seashore areas.
(3) propose one or more mitigation measures to compensate for unavoidable disruption of public access to reefs and seashore areas, whether for fishing or for other purposes.

Therefore, based on the conditional concurrence stated above and the Bureau's review of all other information submitted, we find the application to be consistent with the approved development and resource policies of the Guam Coastal Management Program (GCMP), in accordance with the Coastal Zone Management Act of 1972, (P.L. 92-583) as amended, (P.L. 94-370). The Federal Consistency concurrence, however, does not preclude the need for securing other federal and Government of Guam permits, clearances and approvals prior to the start of this project.

Per 15 CFR §930.4(b), if the requirements for conditional concurrences specified in 15 CFR §930.4(a), (1) through (3), are not met, then all parties shall treat this conditional concurrence letter as an objection pursuant to 15 CFR Part 930 subpart D. Furthermore, if an objection is determined, you are hereby notified that, pursuant to 15 CFR §930.63(e) and 15 CFR Part 930, subpart H, you have the opportunity to appeal an objection resulting from not meeting the requirements of 15 CFR §930.4(a), (1) through (3), to the Secretary of Commerce within 30 days after receiving this conditional concurrence letter, or 30 days after receiving notice from the Federal agency that your application will not be approved as amended by the conditions required by this concurrence.

The proposed action shall be operated and completed as represented in the Coastal Zone Management (CZM) federal consistency determination. Significant changes to the subject proposal shall be submitted to the Bureau for review and approval and may require a full CZM federal consistency review, including publication of a public notice and provision for public review and comment. This condition is necessary to ensure that the proposed actions are implemented as reviewed for consistency with the enforceable policies of GCMP. Guam Land Use

policies (E.O. 78-37), are the federally approved enforceable policies of GCMP that applies to this condition.

Please do not hesitate to contact Mr. Julian Janssen, Federal Consistency Coordinator at 475-9664 or email julian.janssen@bsp.guam.gov or Mr. Edwin Reyes, Coastal Program Administrator at 475-9672 or email edwin.reyes@bsp.guam.gov. *Si Yu'os Ma'åse'.*

Sincerely,

TYRONE TAITANO
Director

SUBJECT: Comments

Reference: Federal Consistency Review GCMP FC2020-0001 Memorandum and Consistency Determination for the Department of the Navy's proposed activities in Mariana Islands Training and Testing (MITT) Study Area

Håfa Adai Mr. Taitano,

After careful review, I find the Department of the Navy's GCMP application for Federal Consistency determination, referenced above, does not sufficiently and thoroughly address the cumulative impacts of the MITT, and other federal actions taken by the Department of Defense, to the integrity of our island's environmental and cultural resources; and to terrestrial and aquatic species and habits. Further, the referenced federal action is inconsistent with Government of Guam commitments to mitigating the effects of climate change, and our responsibility as environmental stewards of the land, air, and water.

I am therefore urging a review of the referenced federal action which, per 40 CFR § 1508.7, takes into consideration the incremental impacts of this federal action when added to other past, present, and reasonably foreseeable future actions taken by federal agencies operating in and around Guam.

The military buildup is one of the most pressing social, political, and environmental issues of our time; and its effects will undoubtedly be felt for decades. In making your determination, I ask that you consider the effects of the ongoing construction of the five live-fire training ranges at Northwest Field, which impact our sacred sites and irreplaceable natural and cultural resources.

RP 1. Air Quality
The Department of the Navy asserts, although most of the training and testing is offshore, where the Clean Air Act National Ambient Air Quality Standards do not apply, air quality of adjacent onshore areas may be impacted depending on the direction of the wind. The Department of the Navy states that "the reasonably foreseeable direct and indirect effect of military training and testing activities on Guam's air quality as a resource of the Guam coastal zone is an increase in air pollutants." The pollutants include regulated or hazardous chemicals derived from detonation of targets, expenditure of fuels that power various vessels, leaks of petroleum from mechanical devices, and use of flares, propellants, projectiles, explosives, and other devices. However, the

Doc. No. 35GL-20-1874.*

Department of the Navy argues that the impact would be minimal due to the distance of most of the activity from shore, "strong ventilation from regional meteorological conditions," and because testing and training activities will not occur simultaneously and continuously. The conclusion based on detailed stressor analysis in the MITT Draft Supplemental EIS that air pollution is minimal, intermittent and short-term does not adequately address cumulative impacts of repeated exposure of the population to criteria air or hazardous pollutants and the resulting health impacts. Moreover, the analysis does not adequately evaluate cascading and cumulative impacts of deposition of air pollutants on land, water, terrestrial and aquatic organisms, and the ecosystem as a whole. Further, my office urges that baseline health conditions of the population and the environment, pertaining to impacts of air pollution, are established at this time to adequately monitor future cumulative impacts.

Additionally, studies of proposed action at sites within the coastal zone of Guam outside of the non-attainment zone for sulfur dioxide and other criteria pollutants due to proposed activities were not addressed in the application. The methodology for determining *de minimus* needs to be clarified. I would highly recommend a determination based on bioaccumulation of pollutants as a means of determining cumulative impacts of air pollutants.

RP 2. Water Quality

This section lacks evidence to support the claim that impact would be in compliance with existing federal statutes and regulations in the context of Guam. The narrative provided focuses on limited studies conducted in non-jurisdictional locations that may or may not be applicable to local conditions. I recommend that local studies be conducted by different researches using different approaches and that results are shared for proper evaluation of the impacts to water quality.

RP 3. Fragile Areas

More than seventy-nine (79) ancestral and historic sites will be adversely impacted at or near *Litekyan*, fourteen (14) historic sites have already been destroyed, and eighteen (18) inadvertent discoveries of human remains have been found since 2018 in the course of the military buildup on Guam. Further, the construction of a fifth firing range requires the clearing of primary limestone forest that is habitat for at least eleven (11) endangered or threatened species, some of which are found nowhere else in the world—effectively jeopardizing the survival of these species.

RP 4. Living Marine Resources

The Department of the Navy lists stressors to marine mammals from the Proposed Action "include acoustic (sonar and other transducers, vessel noise, aircraft noise, weapons noise), explosives (in-water explosions), energy (in-water electromagnetic devices and high-energy lasers), physical disturbance and strike (vessels and in-water devices, military expended materials, seafloor devices), entanglement (wires and cables, decelerators/parachutes), ingestion (military expended materials - munitions, and military expended materials - other), and secondary (impacts on habitat, impacts on prey availability)" which will affect ESA-listed marine mammals. Despite recent studies indicating strandings of marine mammals in the Marians occurring within six (6) days of Navy sonar operations, the Department of the Navy concludes that "no mortalities" will occur from the Proposed Action. This is highly questionable, as is their assertion that the "maximum extent practicable" can sincerely provide protection for living marine resources in our waters.

194 Hernan Cortes Avenue, Terlaje Professional Building, 1st Floor, *Hagåtña*, Guam 96910
671.989.2968•office@senatorperez.org•

RP 7. Public Access

The Department of the Navy deems RP 7 "not applicable" to the Proposed Action. However, bearing in mind once more that such actions should be reviewed in context to cumulative impacts, I must object to this assertion and refer again to *Litekyan*, which is adjacent to the live-fire training ranges and designated as critical habitat for three protected species. The ranges, when fully operational, will limit public access to the area for up to 39 weeks of the year. As well, the Surface Danger Zone of the range extends beyond the land and up to five (5) miles from the shore, restricting access to the waters by Guam fishermen. With this in mind, I find the Department of the Navy's application insufficient.

With these comments in mind, I respectfully urge the Bureau of Statistics and Plans to review the Department of the Navy's GCMP application for Federal Consistency determination in context with the cumulative impacts of all past, present, and forseeable federal actions.

Sincerely,

Sabina F. Perez

MEMORANDUM

TO: Director, Bureau of Statistics and Plans (BSP)

FROM: Administrator

SUBJECT: Comments

Reference: Federal Consistency Review GCMP FC2020-0001 Memorandum and Consistency Determination for the Department of the Navy's proposed activities in Mariana Islands Training and Testing (MITT) Study Area

Hafa Adai Mr. Taitano,

The Guam Environmental Protection Agency has reviewed the Navy's GCMP application for Federal Consistency determination, referenced above, and provides the following comments:

RESOURCES POLICIES (RP):

RP 2. Water Quality

Reference is made to the comprehensive water quality impact analysis of the Proposed Action presented in Section 3.1 (Sediments and Water Quality) of the MITT Draft Supplemental EIS/OEIS. Additional supporting information regarding the water quality assessment is summarized in the application on pages 7-9. These cited research and case studies are used to demonstrate that the Proposed Action would be fully consistent with the GCMP enforceable policy to ensure safe drinking water and protection of aquatic recreation sites from uses and discharges that pose a pollution threat to Guam's waters, particularly in estuaries, reefs, and aquifer areas.

The Navy stated in its application that activities including the use of explosives and explosion byproducts, military materials with metal components, and chemicals other than explosives would occur in federally owned submerged land, or more than 3 NM off shore, thus outside of Guam's coastal zone. Impacted sediments and water quality would only be immediately adjacent to the munition, hence activities would have no significant effect on sediments and water quality within Guam's coastal zone. Furthermore, the Navy concluded that neither state nor federal standards or guidelines would be violated by the chemical, physical, or biological changes in sediment or water quality measureable at the detonation site. The Navy

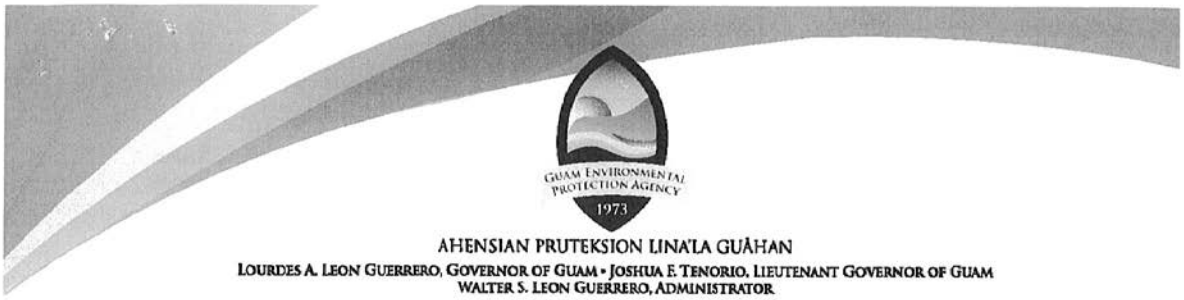
ALL LIVING THINGS OF THE EARTH ARE ONE • *MANUNU TODU I MANTÅLATA*
Like and follow guamepa



should provide a map delineating the Agat Bay and Piti underwater Mine Warfare detonation sites which it states are outside of Guam's coastal zone.

The Navy should continue to conduct water quality impact analysis to demonstrate that explosives and explosive byproducts, metals and other materials expended during training and testing described in the MITT Final Supplemental EIS/OEIS would not exceed regulatory thresholds and guidelines [Sediment chemical characterization methods in Guam Water Quality Standards (2017) and USEPA established criteria for concentrations of explosives, explosive byproducts and metal in saltwater] established for measuring impacts on sediment and water quality.

Guam EPA is concerned that there was no discussion of marine debris cleanup as a result of the MITT activities once completed. The MITT Final EIS/OEIS 2015 (p. 3.1-55) discusses other materials as follows: Other military expended materials include plastics, marine markers, flares, and chaff. Some expended plastics from training and testing activities are unavoidable because they are used in ordnance or targets. (Although plastics are resistant to degradation, they do gradually break down into smaller particles because of sunlight and mechanical wear (Law et al. 2010). Thompson et al. (2004) found that microscopic particles were common in marine sediments at 18 beaches around the United Kingdom. They noted that such particles were ingested by small filter and deposit feeders, with unknown effects.) Targets, however, would typically be recovered following training and testing activities. Chaff fibers are composed of nonreactive metals and glass, and would be dispersed by ocean currents as they float and slowly sink toward the bottom. The fine, neutrally buoyant chaff streamers would act like particulates in the water, temporarily increasing the turbidity of the ocean's surface. The chaff fibers would quickly disperse, and turbidity readings would return to normal.

Section 2 of the 2019 MITT Draft Supplemental EIS/OEIS describes the *annual* Proposed Action and Alternatives. However, the MITT has a five year term. Cumulative impacts of the Range activities, in terms of the number of Ordnances (or other expended items, if any) should be considered **over 5 years**, On-going versus Alternative 1 and Alternative 2. Tables 2.5-1 and 2.5-2 (beginning on page 2-26) compare the proposed SEIS/OEIS action alternatives (Alternative 1 and Alternative 2) with on-going training and testing activities. Each table describes the activities in terms of the activity name and where in the Study Area the Navy proposes to conduct it (first two columns). The next two columns show the **annual** occurrence and ordnance or other expended items (if any) involved in the activity as is currently ongoing (under the heading "2015 MITT EIS/OEIS Ongoing Activities".) The final two pairs of columns present the same information (**annual** occurrence and ordnance/items) as the activities are analyzed in the 2019 Supplemental EIS/OEIS for Alternative 1 and Alternative 2, respectively. As an example, page 2-33 has a Surface Warfare range activity located 12 NM from land. Ongoing activities list 242 events per year (1,210 over 5 years) and **48,040** small caliber rounds *annually* (or **240,200** small caliber rounds **over 5 years**). The number of rounds increases in the Alternative 1 & 2 scenarios to **128,400** small caliber rounds *annually* or **642,000 small caliber rounds over 5 years.** The narrative in Section 4.4.1, Sediment and Water Quality, concludes that proposed changes in training and testing activities under Alternative 1 or Alternative 2 would be *negligible*.

AHENSIAN PRUTEKSION LINA'LA GUÅHAN
LOURDES A. LEON GUERRERO, GOVERNOR OF GUAM • JOSHUA F. TENORIO, LIEUTENANT GOVERNOR OF GUAM
WALTER S. LEON GUERRERO, ADMINISTRATOR

MEMORANDUM

TO: The Honorable Lourdes A. Leon Guerrero, Maga'hågan Guhåhan

FROM: Acting Administrator, Guam EPA

SUBJECT: Agency's Comments to the 2019 Mariana Islands Training and Testing Supplemental EIS/OEIS (MITT).

Transmitted via hand delivery and email: tony.babauta@guam.gov

Hafa Adai Maga' Håga,

In response to the Governor's Circular (GC) #2019-018, requesting comments on the 2019 Mariana Islands Training and Testing Supplemental EIS/OEIS (MITT), below are the Agency's comments. Several comments pertain to the 2015 Mariana Islands Training and Testing EIS/OEIS (2015 MITT), as well as the 2019 MITT Supplemental, as we feel these issues have not been specifically addressed.

1. The Navy does a respectable job of notifying the local regulatory agencies of upcoming underwater Mine Detonation activities within Outer Apra Harbor and Agat Bay. But the public nor the regulatory agencies ever receive any form of feedback/after action reports on outcome of these activities. Specifically if any environmental damages occurred. Guam EPA request that some form of report be produce outlining these activities and highlight any issues regarding water quality, fish kills, protected species sightings, and marine debris be made available to the public and local agencies.

2. In the past, pre-coordination meetings on these activities were conducted with the local regulatory agencies. Guam EPA requests to make these meetings standard operating procedures, at a minimum of bi-annual basis.

3. At a minimum, a yearly report should be produced summarizing all activities identified in the MITT. There is no current mechanism to evaluate if the activities and quantities identified in the MITT are met or exceeded. Report should also address any impacts to stressor types.

4. Neither the 2015 MITT nor the 2019 Supplemental MITT have a discussion on the rational for an increase from a 10 lbs. underwater mine charge to the new standard of a 20 lbs. charge for the listed mine detonation activities. What is the justification for the increase? This needs to be further explained and justified.

5. In the 2015 MITT, page 3.1-18, Section 3.1.3, it states that Amphibious assaults and raids sediment plumes are temporary and since no military materials are expended, "…no further analysis of this

GUAM EPA | 17-3304 Mariner Avenue Tiyan Barrigada, Guam 96913-1617 | Tel: (671) 300.4751/2 | Fax: (671) 300.4531 | epa.guam.gov

Development and Operating Regulations, Part II: Guidelines for Water Works Development (22 GAR Chapter 7), and the Water and Wastewater Operator Certification Regulations (22 GAR Chapter 11

12. The 2019 MITT Supplemental states there have been no new information since the 2015 MITT, which identifies specific data gaps within the report about the environmental impact of previously used ammunition and/or the degradation products on the marine ecosystems in that area. There needs to be a discussion on this topic.

If you have any questions or concerns, please contact me directly by email at jesse.cruz@epa.guam.gov or by telephone at 671-300-4795.

MEMORANDUM

To: Tyrone Taitano, Director, Bureau of Statistics and Plans (BSP)

From: Paul Kemp, Assistant Manager, Compliance and Safety

Subject: Federal Consistency Review: Department of the navy Proposed Activities in the Mariana Islands Training and Testing (MITT) Study Area GCMP FC- 2020-001

Håfa Adai,

The Guam Waterworks Authority has reviewed the 2019 Draft Mariana Islands Training and Testing (MITT) Supplemental Environmental Impact Statement/Overseas Environmental Impact Statement. The GWA reviews proposed planned military activity to ensure protection of the Northern Guam Lens Aquifer and wastewater discharge into Guam's waters.

Land based training located on Guam was covered under the 2015 MITT Final EIS/OEIS under the existing Mariana Island Range Complex (MIRC). This Supplemental EIS/OEIS considers activities conducted at sea and on Farallon de Medinilla (FDM). This supplemental EIS/OEIS incorporated new models, information, data and science as required by the Council on Environmental Quality Regulations. However, there are no changes made to land based activities proposed on Guam. The analysis on impacts on sedimentation and water quality are assessed for activities that will impact water quality off shore and not impacts to the Northern Guam Aquifer.

The proposed activities listed in this draft MITT Supplemental EIS/OEIS will not have an impact to the ability for GWA to provide safe drinking water to its customers and ensure that wastewater discharge is conducted in appropriate manner.

Sincerely,

Paul Kemp
Assistant General Manager – Compliance and Safety

DOD March 2019

Re: Marianas Island Training and Technology- Comments

Hafa Adai,

The Division of Aquatic and Wildlife Resources has reviewed the proposed Marianas Island Training and Technology and provides the following comments:

1. The Draft Environmental Impact Statement (EIS) for the Marinas Islands Military Testing and Training (MITT) was released and available for public comment.

2. Please be aware that the island and its surrounding marine environment is inhabited by Endangered species of whales and dolphins, and any military activity should be aware of their presence.

3. The action should consider the impact to the marine mammals near Guam. The Division has recorded stranding's of these animals, and should take all precautions not to impact them

DRAFT

March 4,2020

DOD, Ms. Nora Macariola
Naval Facilities Engineering Command, Pacific 258 Makalapa Drive, Suite I00

Attn: MIIT EIS/OEIS Project Manager Email: Marianas.tap.eis@navy.mil

Subject: Comments on the Supplemental Draft Overseas Environmental Impact Statement/Overseas Environmental Impact Statement for the Mariana Islands Training and Testing Activities

Hafa Adai:

The Draft Environmental Impact Statement/Overseas Environmental Impact Statement for the Mariana Islands Military Testing and Training (MIITT DEIS) Volume I and II were released for public review September 13, 2013. The Guam Department of Agriculture, Division of Aquatic and Wildlife Resources requested and received a hard copy of the MIITT DEIS for review pursuant to the National Environmental Policy Act of 1969 [42 U.S.C. 4321 *et seq.;* 83 Stat.852] (NEPA) on November 12, 2013.

The initial action was discontinued. A subsequent was published, and a public hearing was held at the University of Guam's School of Business and Public Administration, Leon Guerero Building, on march 19, 2019, from 5pm-10pm. Public comments were accepted, and DAWR staff attended the meeting.

The proposed action by the US Department of the Navy (DON) includes reevaluation and reauthorization of the training and testing activities reviewed in the Marianas Islands Range Complex (MJRC) in May 2010, with an expansion of the study area to include high seas and transit corridors not previously approved, as well as adjustments to locations and tempo of training and testing activities. The actions are proposed to achieve and maintain military readiness, to support and to conduct current, emerging, and future training and Research, Development, Test and Evaluation activities, while enhancing training resources through investment in Guam and the Commonwealth of the Northern Marianas Islands. The draft MIIT DEIS commit sat-sea and land-based training areas on Guam and CNMI, as well as transit corridors between Guam and CNMI.

As the local state agency mandated to monitor and protect Guam's biological resources, the Guam Department of Agriculture (Dog) submits the following general comments to be addressed in the development of the MITT Final Environmental Impact Statement and Record of Decision. In addition, we have included comments in table form referencing specific document pages (see attachment).

1. First and foremost, DOD needs to provide a progressive, comprehensive plan for the recovery of native species on DOD property in consultation and coordination with DoAg. Without the ability to reintroduce federally endangered species on DOD property the cumulative impacts of DOD actions are jeopardizing the DoAg's ability to recover Guam's native species. Furthermore, DOD's failure to coordinate with DoAg as required by the Sikes Act of 1960 [16 U.S.C. *et seq.;* 74 stat. 1052], as amended, and recognize the DoAg's ability to assist DOD in meeting their Section 7 requirements under the Endangered Species Act of 1973 [16 U.S.C. 1531 *et seq.:* 87 Stat. 884], as amended, results in a waste of taxpayers' dollars. The DoAg further emphasizes the need to be consulted and notified in matters that may impact the natural resources of Guam.

2. Secondly, the Final EIS needs to outline how DON will address long-standing issues regarding timely access for the DoAg Division of Aquatic and Wildlife Resources (DAWR) staff to all DOD lands to monitor and manage Guam's natural resources. The DOAg-DAWR staff could complete monitoring of resources under annual federal funded grant objectives, without cost, or at a much lower cost to DON that is currently being contracted and assist with meeting Sikes Act coordination obligations. The current access requirements for DoAg-DA WR staff are cumbersome and prevent timely coordination as opposed to those procedures for federal employees and contractors.

3. All Navy contractors should communicate with the Division in regards to sensitive areas, resource-wise.

4. The Final MITT DEIS needs to address another long-standing issue that is DOD's failure to comply with local laws. The MITT activities and study area include the Piti Marine Preserve Area that extends to the 600-foot contour. Any take of non-pelagic fishes within this area is a violation of Guam law.

5. The Final MITT DEIS must mitigate the cumulative impacts to recreational ~~fishing in the oceanic areas that will be impacted by the proposed action. The~~ NEPA documents for other proposed military activities indicate the closure of important fishing areas such as Ritidian and Pati Point. The additional loss of key recreational fishing areas proposed in the Draft MITT EIA is unacceptable.

6. Other boaters, including divers and other recreational users, also frequent many areas within the MITT study area. There is no clear indication of how extensive closures will be -do events last for an hour, or a day, or a week? The Final EIS and ROD need to minimize closure of areas regularly used by recreational boaters and identify clearly the space and time of the closures.

DoAg Comments on Draft MITT F2019 OEIS

Page 2

7. When notices to mariners is sent out, DOD should insure that notices are sent out to all media source outlets, to inform the public of Surface-Danger –Zone activities as the actions are implemented. Prior to training exercises, the DON and USCG issue NOTMARs and NOTAMs to announce an exercise and to notify the public of potential hazards in the exercise area. DON must ensure these notices are adequately distributed to the public and with a much larger area proposed in the MITT distribution must be assessed for adequacy.

8. The ROD must clearly indicate how the Micronesia Biosecurity Plan will be implemented, including funding mechanisms, to prevent the spread of invasive alien species (lAS) throughout the region. For example, I 00% inspection rates for brown tree-snake (BTS) at ports of exit from Guam and entry points to other regional areas are necessary to ensure BTS does not impact bird, bat and lizard populations on other islands. These populations are necessary for the recovery of Guam's native ecosystem.

9.

DoAg Comments on Draft MITT F2019 OEIS

Page 2

10. Although there are currently BTS inspections of cargo and vessels from Guam, there is a potential for the system to be overwhelmed by the increase in tempo of activities. The MITT DEIS also needs to be mindful of other IAS that Guam could infect CNMI with that would be devastating to endangered wildlife and Its habitats, i.e., little fire ant and coconut rhinoceros beetle.

11. Consistent monitoring of behavior and distribution of Mariana fruit bat/island swiftlet/common moorhen/megapode (and other terrestrial species of regional concern) must be conducted prior to and after MITT related activities in-order-to evaluate the impact of activities, particularly on species of greatest conservation need. Appropriate measures must be incorporated to reduce impacts to terrestrial species, as well as measures to avoid impacting species that aggregate when feeding in open water ocean. Impacts to aggregations of individuals in the expanded areas of MIIT activities may impact species on a population level.

12. The assessment of potential effects to marine animals and habitat from underwater demolition needs more clarified and analyzed. The habitat mapping needs to be more detailed, the Cetacean species that utilize the area proposed for the MITT need to be identified, as well as the impacts such activity will have on these species. The analysis also needs to include the impacts to sea turtles. The presence of ESA-listed sperm whales is well documented within three to five miles offshore in the Agat area. Effects to this species and the m itigation for these actions are not addressed in the MITT DEIS. The increased boat activity greatly increases the potential for boat strike of sperm whales. Navy lookouts undergo extensive training in order o qualify as a watch stander. It seems the use of these watch standers been how successful & should be measured.

I0. DoAg is concerned about the impact of landing craft exercises on the dolphins that reside in Agat Bay. The DON contended unavoidable impacts. The Navy recognizes the common occurrence of spinner dolphins within Agat Bay and has developed mitigation measures in consultation with NMFS under provisions of the MMPA. Beachmasters are shore-based observers with binoculars whose sole purpose is to ensure safety of craft including avoidance of marine and terrestrial animals. Beachmasters were to work with environmental monitors and the natural resource managers. These measures have been utilized - how successful have they been and how has that success been measured?

Doc. No. 35GL-20-1874.*

The MITT DEIS must address impacts to the existing community of resource users and the need to mitigate economic impacts by avoiding near shore populations and their habitats. The training activities themselves present additional challenges that may alter

MEMORANDUM

To: Director, Bureau of Statistics and Plans

From: Acting Director, Department of Parks and Recreation

Subject: Federal Consistency Review: Department of the Navy Proposed Activities in the Mariana Islands Training and Testing (MITT) Study Area GCMP FC2020-0001

Dear Mr. Taitano,

We have reviewed the subject Federal Consistency Application for the Department of the Navy proposed activities in the Mariana Islands Training and Testing (MITT) Study Area and have the following comments:

1. In response to your request we reviewed the enforceable policies pursuant to the Executive Order 78-37, Guam Land Use Policies. We are currently working to assess and mitigate any adverse effects to historic properties with the Department of the Navy (DoN).

2. We have had Section 106 consultations with the DoN, expressing our concerns with regards to the project's potential to affect historic and archaeological sites within the project's areas of potential effect (APE). At this time, we are working off of a 2009 Programmatic Agreement (PA) extension, while the affects to historic properties are being assessed by the DoN. We are working to have a new PA that will address any and all adverse effects to historic properties within the near future.

Based on the aforementioned, we have not completed our consultation on the affects to historic properties and, therefore, we cannot agree with a Federal Consistency Determination for the subject undertaking.

Should you have any questions with regards to our comments, please contact Mr. John Mark Joseph, State Archaeologist, at 475-6339.

Sincerely,

Jesse G. Garcia

Director, Office of Protected Resources
National Marine Fisheries Service
National Oceanic and Atmospheric Administration
B-SSMC3, Room 13821
1315 East-West Highway
Silver Spring, MD 20910-3282

Dear Director:

SUBJECT: REQUEST FOR INITIATION OF ENDANGERED SPECIES ACT SECTION 7 FORMAL CONSULTATION FOR COMMANDER, UNITED STATES PACIFIC FLEET TRAINING AND TESTING ACTIVITIES

In accordance with section 7 of the Endangered Species Act (ESA), the U.S. Navy requests initiation of formal consultation on the Mariana Islands Training and Testing (MITT) activities occurring within the Pacific Ocean in the surrounding waters of the Mariana Islands.

The proposed action may affect listed species that reside within the MITT Study Area by exposing them to sound and other environmental stressors associated with training and testing activities. The enclosed Biological Assessment (BA) is the Navy's primary document that provides the required information pursuant to 50 C.F.R. §402.12(f). The U.S. Navy is requesting formal consultation on Alternative 2 within the MITT Draft Supplemental Environmental Impact Statement/ Environmental Impact Statement (EIS/OEIS).

The Navy is requesting formal consultation on ESA-listed species including the blue whale (*Balaenoptera musculus*), fin whale (*Balaenoptera physalus*), humpback whale (*Megaptera novaeangliae*) from the Western North Pacific Distinct Population Segment (DPS), sei whale (*Balaenoptera borealis*), sperm whale (*Physeter macrocephalus*), green sea turtle (*Chelonia mydas*) from the Central West Pacific DPS, East Indian-West Pacific DPS, and North Central Pacific DPS, hawksbill sea turtle (*Eretmochelys imbricata*), leatherback sea turtle (*Dermochelys coriacea*), loggerhead sea turtle (*Caretta caretta*), olive ridley sea turtle (*Lepidochelys olivacea*), giant manta ray (*Manta birostris*), oceanic whitetip shark (*Carcharhinus longimanus*), scalloped hammerhead shark (*Sphyrna lewini*) from the Indo-West Pacific DPS, and three coral species *Acropora globiceps*, *Acropora retusa*, *Seriatopora aculeata* (no common name).

Doc. No. 35GL-20-1874.*

5090
Ser N465/0703
18 June 2019

The Navy also seeks concurrence on our high-energy laser No Effect determinations for coral, giant manta rays, oceanic whitetip sharks, and hammerhead sharks.

High-energy lasers are a new testing activity not analyzed in previous consultations between the Navy and National Marine Fisheries Service (NMFS) within the MITT Study Area. High-energy laser weapons are designed to disable surface targets, rendering them immobile. These laser systems are extremely unlikely to strike the water directly, since that is not an aimpoint for the system. Even though the probability is very low, if there is a target miss by the laser, a laser beam would typically intersect the water surface in the 200 m (219 yds) to 6.5 km (3.5 NM) range or more. At these ranges, the low angles to the water will reflect most of the laser energy. The little remaining laser energy after reflection that might enter the water would do so at much lower power levels, reaching eye-safe levels within 0.3 m (12 in) of the surface at 200 m (219 yds) and within 0.18 m (7 in) at 1 km (0.5 NM). Unlike marine mammals and sea turtles that surface to breath, ESA-listed fish would normally be found at depths greater than 7-12 inches over most of their distribution.

There are additional layered safeguards on these systems that further reduce the probability of a water strike. First, the system will only fire when the operator pulls the trigger. Second, the system has provisions that only permit firing when locked onto a target and automatically interrupts firing if the target track is lost. This gives the operator time to reacquire the target lock before firing again. Third, the operator is also trained to stop firing when the laser aim point moves off the selected target in the event the automated system does not turn the laser off first. Even if at the water surface, such as when a shark's dorsal fin is above water, the depth of a given shark's body would still mean eyes and other sensitive organs would be deeper than 7-12 inches. Given these high-energy laser procedural measures and technological characteristics, the low probability of laser energy accidentally hitting the water surface, the low power of a laser if it did hit the water and limited penetration depth, effects on ESA-listed fish species are not expected to occur.

The Navy also seeks concurrence on our simulant No Effect determinations for all species. Simulants are another new testing activity not analyzed in previous consultations between the Navy and NMFS within the MITT Study Area.

The Navy uses compounds, referred to as simulants, as substitutes for chemical and biological warfare agents to test equipment intended to detect their presence. Simulants must have one or more characteristics of a real chemical or biological agent-size, density, or aerosol behavior to effectively mimic the agent, but must also pose a minimal risk to health and the environment in order to be used safely in outdoor tests. They are relatively benign compounds (e.g., oil of wintergreen) that disperse as an aerosol and are expected to dissipate before hitting the water. Exposure levels during testing activities would be well below concentrations associated with any adverse health or environmental effects. The degradation products of simulants used during testing would also be harmless. Given these characteristics of simulants used during testing activities, no effects are expected on any ESA-listed species.

21 November 2019

Assistant Regional Administrator, Habitat Conservation Division
Pacific Islands Regional Office, National Marine Fisheries Service
1845 Wasp Boulevard, Building 176
Honolulu, HI 96818-5007

Dear Director:

SUBJECT: SUBMISSION OF 2019 NAVY SUPPLEMENTAL ESSENTIAL FISH HABITAT ASSESSMENT IN SUPPORT OF THE MARIANA ISLANDS TRAINING AND TESTING SUPPLEMENTAL ENVIRONMENTAL IMPACT STATEMENT/ OVERSEAS ENVIRONMENTAL IMPACT STATEMENT

This letter provides the Pacific Islands Regional Office (PIRO) of the National Marine Fisheries Service with supplemental information for the U.S. Navy's continuing training and testing activities previously analyzed in the 2015 Mariana Islands Training and Testing (MITT) Environmental Impact Statement/Overseas Environmental Impact Statement (EIS/OEIS).

In support of the 2015 EIS/OEIS, the Navy also prepared an Essential Fish Habitat Assessment (EFHA) in May 2014 analyzing potential impacts of Navy activities on designated EFH within the MITT Study Area in accordance with the Magnuson-Stevens Fisheries Conservation and Management Act of 1976, Public Law 94-265 as amended through January 12, 2007, section 305(b)(2) and 50 C.F.R 600. The 2015 EIS/OEIS and associated EFHA was subject to PIRO EFH consultation concluding in August 2014.

The U.S. Navy prepared a draft supplemental MITT EIS/OEIS using new information available after the release of the 2015 EIS/OEIS to cover similar activities from November 2020 and into the reasonably foreseeable future (https://mitt-eis.com). With few exceptions, there are no substantive changes to activities and their impacts, to the geographic extent of these activities, or to designated EFH areas in the MITT Study Area that would alter the conclusion from the 2014 EFHA or affect the basis for PIRO's previous EFH Conservation Recommendations.

The U.S. Navy requests reinitiation of a MITT supplemental EFH consultation pursuant to 50 C.F.R. 600.920(a)(1) to address only the changes in proposed activities that may adversely affect EFH as well as any new information that affects the basis for NMFS EFH Conservation Recommendations. A new supplemental EHFA has been prepared to support this request (Enclosure 1).

Pearl Harbor, HI 96860-3131

December 19, 2019

Dear Mr. McNair:

The National Marine Fisheries Service, Pacific Islands Regional Office (NMFS), received a request from your staff at the Commander, U.S. Pacific Fleet (hereafter, Navy) to complete a supplemental essential fish habitat (EFH) consultation for updates to the Mariana Islands Training and Testing (MITT) Environmental Impact Statement (EIS)/Overseas EIS (OEIS). The scope of the supplemental consultation includes aspects of the proposed activities that have changed since the 2014 EFH consultation was completed, and incorporation of any new scientific information that changes the basis of prior conservation recommendations. The Navy requested that the consultation be completed by December 21, 2019, and NMFS appreciates this opportunity to coordinate with the Navy and provide revised conservation recommendations pursuant to the Magnuson-Stevens Fisheries Conservation and Management Act (Magnuson-Stevens Act), Section 305 (b) (2) and 50 C.F.R 600.920.

Overview

In order to streamline the MITT supplemental EFH consultation, all supporting materials and analysis from the 2014 consultation are incorporated by reference 50 CFR 600.920(e)(5). Project activities and methods are superseded only where new information has been provided by the Navy; however, NMFS will consider sources of scientific information that may be new. The ten conservation recommendations from 2014 still apply, and will be revised only where these new sources of supplemental information change the basis for NMFS determination.

Doc. No. 35GL-20-1874.*

Essential Fish Habitat

The marine water column from the surface to a depth of 1,000 m from shoreline to the outer boundary of the Exclusive Economic Zone (5,150 kilometers/200 nautical miles/230 miles), and the seafloor from the shoreline out to a depth of 400 m around each of the Mariana Islands, have been designated as EFH. As such, the water column and bottom and all surrounding waters and submerged lands within the Mariana's Archipelago are designated as EFH and support various life stages for the management unit species (MUS) identified under the Western Pacific Regional Fishery Management Council's, Pelagic and Mariana Archipelago Fishery Ecosystem Plans (hereafter, Mariana FEP). The MUS and life stages found specifically within the Mariana's Archipelago include eggs, larvae, juveniles, and adults for Bottomfish and Pelagic MUS. Habitat Areas of Particular Concern (HAPCs) only occur for these MUS within the Marianas. Specific types of habitat considered as EFH include coral reef, patch reefs, hard substrate, artificial substrate, seagrass beds, soft substrate, mangrove, lagoon, estuarine, surge zone, deep-slope terraces and pelagic/open ocean.

Ecological Roles

The principal benthic organisms provide ecological services (e.g., water filtration and maintaining balanced nutrient concentrations) and provide physical habitat at both micro- and macro-scales. At a micro scale, the shape of benthic organisms change water movement, which can influence the settlement (McDougall 1943) and behavior of larvae and the availability of planktonic prey (Williams 1964). Sessile organisms provide refuge from predators, particularly for larvae and small sized species (Russ 1980; Sutherland 1974). Sessile organisms provide new ecological niches increasing species diversity. At a macro-scale, corals are the primary habitat builders in the coral reef ecosystem that benefit juvenile, sub-adult, and adult life stages of the MUS that utilize this designated EFH. The morphology, shape, and composite features of benthic organisms can also influence feeding strategies of these MUS.

NMFS Concerns

Adverse Effect Determinations

This EFH supplemental consultation incorporates by reference all information previously provided from previous phases of MITT activities, except were new information has been provided. In addition, all previous determinations and conservations recommendations apply except where explicitly amended. NMFS has determined that the activities described within the Supplemental MITT EFHA may result in adverse effects to EFH, and has provided seven new conservation recommendations to help avoid, minimize, offset for, or otherwise mitigate potential impacts.

NMFS categorizes adverse effect types in four categories: temporary, short-term, long-term, and permanent. The severity is measured by intensity and spatial extent of the stressor, while the adverse effect type is based on the recovery rate from the impact and the pervasiveness of the impact at the

ecological scale. Standard EFH effects analysis normally will use the most sensitive and hard-to-replace EFH resources based on the recovery time back to the baseline or the highest following stable state likely. Considering recruitment and growth rates of impacted fauna, oceanographic and geomorphologic features, and anticipated future conditions, living EFH resources which are altered or lost can be quantified as a debt. Non-living resources can also be adversely affected and lost, such as removal or impairment of feature to serve as shelter. These types of effects tend to be permanent.

The threshold for what effects are considered adverse to EFH is highly variable among the hundreds of species managed by the Western Pacific Fishery Management Council and NMFS. For example, multiple species included in each of the MUS in all FEPs have strong associations with the water column, especially the water surface in their egg and larval life stages. Those species typically have eggs that float very close to the surface (buoyant) and/or become planktonic as larvae. Therefore, physical disturbance of the surface (e.g., boat propeller churning) may be an adverse effect to the water column, which may reduce the fecundity of both MUS, their prey, and habitat forming organisms (e.g., coral). Both power generation studies (Schlezinger et al., 2013) and those that investigate the impacts of boating on zooplankton (Bickel et al., 2011) provide useful proxies in this respect. However, the severity of those potential adverse effects are dependent upon many factors that are complex to predict, including but not limited to: the reproductive cycles of a diverse assemblage of organisms potentially affected, oceanographic conditions (e.g., tides, prevailing currents, nearshore eddies), and the frequency of and forces generated by the vessels being operated.

The Navy provided a summary table of adverse effects determinations within the supplemental EFHA that are inconsistent with the definition of adverse effect in the Magnuson-Stevens Act (50 C.F.R. § 600.810). NMFS does not agree with the 'no effect' determinations made for acoustic, explosive, or physical disturbance and strike stressors. Below we list select stressors from Table 5-1 of the supplemental EFHA, followed by a description of how these stressors may impart temporary, short-term, long-term, permanent, and cumulative adverse effects on EFH (see *EFH Stressors* section below). My staff is willing to investigate more specific descriptions of adverse effects determinations for the stressors summarized in this document, if the Navy initiates an expanded EFH consultation.

Acoustic

The Navy lists sonar, vessel noise, and weapons noise as acoustic stressors. The Navy uses sonar (underwater sound) to navigate, communicate, or detect underwater objects. Active sonar emits sound waves which reflect off objects and returns to the receiver whereas passive sonar uses listening equipment to pick up underwater sounds (MITT EFH Assessment 2014). Vessels will be used for the majority of all proposed activities. Noise will be discharged from vessel engines during maneuvers and staging. Vessel noise can adversely affect fish and coral recruitment (see below). The use of sonar and weapons noise may result in temporary acoustic impacts to water column EFH, as it will alter the natural soundscape affecting the quality of water column EFH.

Explosives

Underwater explosive and other impulsive activities include ordnance and munitions such as projectiles, missiles, bombs, and other munitions (e.g. demolition charges). Explosives detonated near the surface would result in a shock wave and recurring pressure waves in the water column Although most explosives would be at or below the water surface, charges associated with mine neutralization could occur near the ocean bottom. Temporary physical and acoustic effects to water column EFH will occur from explosives detonated near the surface. Explosives detonated near the bottom may result in physical impacts to benthic communities, increase in turbidity (through disturbance of seafloor), and increase in acoustic impact. Physical impacts to soft bottom will be short-term, including an increase in turbidity, whereas physical impact changes to hard bottom will be permanent. Temporary effects to fish may be change in fish behavior or distribution, and permanent effects may be fish mortality.

Physical Disturbance and Strike

The Navy includes vessel movement, in-water devices, military expended materials, seafloor devices, and personnel disturbance as stressors under this category. Vessels are used in nearly all training and testing activities and include multiple types of vessels such as aircraft carriers, surface combatant, amphibious warfare ships, support crafts, and submarines Vessels that approach the shore or beach such as amphibious vessels could cause physical effects to benthic communities; physical impacts to soft-bottom will be short-term, including an increase in turbidity, whereas physical impact changes to hard bottom will be permanent. In 2017 a French Navy vessel grounded at Jade Shoals on Guam during military exercises and damaged the reef, highlighting the need for a funded vessel grounding response plan to ensure quick removal of the vessel, documentation of damages and offset of any permanent loss.

Military expended materials include: non-explosive practice munitions, fragments from high explosive munitions; and expended materials other than ordnance, such as sonobuoys, ship hulls, expendable targets and aircraft stores (fuel tanks, carriages, dispensers, racks, carriages or similar types of support systems on aircraft which could be expended or recovered Materials that are not recovered will result in marine debris that will either sink to the bottom or float and be transported by wind and ocean currents. Debris that sinks will result in permanent physical impacts to benthic habitat. Although ingestion rates are lower than sea turtles and marine mammals, ingestion of marine debris has been documented in approximately 40 fish species (CBD 2012).

Seafloor devices are items that are deployed onto the seafloor and may later be recovered, including moored mine shapes, anchors, bottom placed instruments, and robotic vehicles referred to as "crawlers." Seafloor devices are either stationary or move very slowly along the bottom Physical impacts to soft bottom will be short-term, including an increase in turbidity, whereas physical impact changes to hard bottom will be permanent.

4

Energy

Electromagnetic devices use magnetic influence in activities such as mine neutralization and mine countermeasure activities. The majority of the activities include towed or unmanned mine warfare systems that mimic the electromagnetic signature of a passing vessel which may result in temporary behavioral effects to susceptible fish and invertebrates.

EFH Stressors

The proposed MITT activities may result in adverse effects to EFH including physical impacts to benthic communities, enhanced sedimentation and turbidity, enhanced chemical contaminants, increase in acoustic and energy impacts, and introduction and propagation of invasive species. Any proposed activity that occurs within designated EFH may cause the following adverse effects, described generally in this section. The extent and severity of individual stressors will be highly variable across the spectrum of MITT activities, and the adverse effects may not be consistent from year to year even though the activities remain the same, due to external factors (i.e., climate change).

Physical Impacts to Benthic Communities – Physical damage to coral or coral reefs is often associated with the breaking of colonies or in the form of abrasion. The amount of damage is dependent on many factors, but is mostly due to the nature of the physical force and the types of corals being impacted (Storlazzi *et al.* 2005, Shimabukuro 2014). Corals, which are primarily responsible for the structural complexity of coral reefs, are particularly vulnerable to physical damage because their slow-growing carbonate skeleton is relatively brittle and their polyps are easily damaged. In general, lobate, encrusting, and other massive colony morphologies tend to withstand breakage better than foliose, table, plating, and branching morphologies; more fragile forms tend to have higher growth rates (Rützler 2001). Reduction of topographic complexity in the habitats of the coral reef ecosystem reduces biodiversity and productivity (Alvarez-Filip et al. 2009). In 2017, a MITT-related vessel grounding occurred in the nearshore coral reef ecosystem of Guam, resulting in the long-term to permanent loss of coral ecosystem services and function due to the absence of contingency/response planning and sufficient offset.

NMFS has reviewed the Navy's approach to managing the risk from physical impacts to EFH, including corals, associated with explosive stressors, vessel movements, and personnel disturbance. NMFS agrees that the proposed BMPs will help to avoid and minimize some impacts. However, NMFS still has concerns regarding the proposed increased usage and the lack of updated benthic mapping and surveys at the Guam UNDET site. We are also concerned about the ability of personnel and small boats to consistently remain within designated approach pathways during beach assault training activities. We also see a need to formalize planning and funding for response, assessment, and mitigation following potential vessel grounding events. In addition to direct physical damage from a grounding, these events break down the reef into rubble, which then becomes a long-term scouring hazard with the potential to induce further physical damage to corals due to wave action.

5

Increase in Sedimentation and Turbidity – Suspended sediment can elicit short- and long-term responses from aquatic organisms depending on the quantity, quality, and duration of suspended sediment exposure (Kjelland et al. 2015, Philipp and Fabricius 2003). Coral reef organisms are easily smothered by sediment (Golbuu et al. 2003), and rates >100 milligrams/centimeter^2/day can kill exposed coral tissue within a few days (Riegl and Branch 1995), although corals show considerable interspecific variability. Sedimentation can also reduce photosynthetic rates (Philipp and Fabricius 2003), disrupt polyp gas exchange, inhibit nutrient acquisition (Richmond 1996), cause tissue damage (Rogers, 1990), reduce recruitment success (Gilmour 1999) and increase metabolic costs due to enhanced mucus production (Telesnicki and Goldberg 1995).

NMFS has reviewed the Navy's approach to managing the risk from sediment and turbidity to EFH, including corals. We remain particularly concerned about these stressors at the Guam UNDET site due to the proposed increase in tempo and usage in the nearshore ecosystem, where there is a lack of updated benthic habitat mapping and coral reef surveys. Due to uncertainty from the lack of recent, quantitative resource survey assessment and geomorphologic information, NMFS must assume that enhanced sedimentation and turbidity will result in potential mortality and the degradation in the condition of corals present. New surveys and updated benthic habitat maps may help to alleviate these concerns.

Increase in Noise – Noise has a broad range of potential effects, especially when it is very loud and has high amplitude (Casper *et al.* 2016), or when it is less intense but long-lasting (Popper and Hastings 2009). Behavioral changes can occur, resulting in animals leaving feeding or reproduction grounds (Slabbekoorn et al., 2012) or becoming more susceptible to mortality through decreased predator-avoidance responses (Simpson et al., 2016). Less intense but chronic noise can cause a general increase in background noise over a large area. Chronic noise will not likely result in mortality, but may mask biologically important sounds and alter the natural soundscape, cause hearing loss, and/or have an adverse effect on an organism's stress levels and immune system (Minton 2017). Masking of the normal reef sounds by artificial sounds may have an impact on species abundances and numbers on coral reefs. Research has shown that larvae of several reef fish families preferentially select traps emitting high frequency sounds over traps emitting sounds similar in frequency to normal background frequencies (Simpson *et al.* 2008). Studies on an invertebrate species has shown that chronic exposure to noise may lead to increased metabolic rates, causing a reduction in growth and reproduction (Lagardère 1982). Recent advances in passive acoustic technology and analysis indicates that coral reef larvae are using lower frequency sounds such as those made by grunting fishes. These daily sounds are primarily produced at night and during dusk and dawn. However, these types of sounds are produced most abundantly during spawning. Corals exposed to enhanced anthropogenic noise, including that from vessel engines, will have disrupted settlement of their planulae (Lecchini et al. 2018).

NMFS disagrees with the Navy's conclusion that noise generated as part of MITT activities will have no effect on EFH. There are reasonable avoidance and minimization measures that can be

implemented to reduce adverse effects to coral, bottomfish life history stages, and organisms that serve as prey-base for bottomfish. Some of these measures include establishing avoidance/buffer zones and turning off vessel engines (particularly small vessels in nearshore ecosystems) and sonar when not needed.

Invasive Species – Introduced species are organisms that have been moved, intentionally or unintentionally, into areas where they do not naturally occur. Species can be introduced to new biogeographies, typically via transport on vessel hulls or in ballast water, such as those that may be used in the Applicant's cable laying and trenching operations. Invasive species rapidly increase in abundance to the point that they come to dominate their new environment, creating adverse ecological effects to other species of the ecosystem and the functions and services it may provide (Goldberg and Wilkinson 2004). Invasive species can decrease species diversity, change trophic structure, and diminish physical structure, but adverse effects are highly variable and species-specific.

NMFS is concerned that the increase in vessel movements and personnel disturbances proposed within the MITT may also increase the risk of introducing and spreading invasive species within the region through direct physical introduction or transportation resulting from hull fouling and ballast water. A description of how the Navy plans to avoid and control for the possible spread of invasive species during these activities would help alleviate this concern.

Cumulative Adverse Effects

A cumulative effects analysis must consider the changes to the marine environment that are expected to occur under our current climate trajectory. Considering that many effects in marine ecosystems have long durations due to slow ecosystem recovery (e.g., corals), activities proposed today could result in significant and irreversible damage to EFH in coming decades. In addition, individual adverse effects (stresses) often interact in ways that increase adverse effects (Brown 1997, Negri and Hooganbloom 2011). For example, elevated seawater temperatures can cause coral bleaching, but the temperature threshold at which coral bleaching occurs is lowered under elevated nutrient conditions. In another example, nutrient enrichment combined with large-scale physical damage can increase the probability of a shift in dominance from coral to algae, known as "phase-shifts."

Crain *et al.* (2008) reviewed over 200 studies examining cumulative effects for multiple stressors in intertidal and nearshore marine ecosystems to elucidate general patterns in cumulative stressor effects. The cumulative effects of any two stressors were distributed among all interaction types with 26% being additive, *i.e.*, no interaction, 36% synergistic and 38% antagonistic. In 62% of all cases, interactions between stressors resulted in an adverse effect on the species or ecosystem that was at least additive. In cases where a third stressor was considered, over two-thirds of the interaction became more negative, and the number of synergistic interactions increased to 66% of the cases.

7

The amount of Navy materials being deposited (i.e., MEM) is planned to continue for the foreseeable future. At an unidentified inflection point adverse effects to EFH from the continual deposition of these materials over the same footprint will be reached. As that point is approached it will become more difficult to mitigate and restore ecological functions and services. We expect that the Navy will calculate the deposition rates and decomposition rates to determine maximum MEM loads as this action becomes decadal, since offset may become appropriate if MEM loading impairs the habitat function. In addition, there may be cumulative adverse effects from personnel usage and unexpected vessel groundings in the absence of proper contingency planning, including resources for regular and on-the-spot survey damage assessments at all sites used for amphibious assaults.

NMFS is concerned about past, present, and future adverse effects to EFH resources from these stressors. The concerns about MEM can be assessed through the Navy's calculation of deposition and decomposition rates to determine maximum MEM loads as this action becomes decadal; this would inform potential offset. Quantitative resource survey assessments, updated benthic habitat substrate and biological cover mapping, and vessel grounding planning and contingencies would help to avoid, minimize, offset for, or otherwise mitigate potential cumulative adverse effects from these stressors.

Revised Conservation Recommendations

NMFS provides the following supplemental EFH conservation recommendations in accordance with the EFH provisions of the Magnuson-Stevens Act (50 C.F.R. 600.920) to help Navy ensure that adverse effects to EFH including coral reef resources are avoided, minimized, and offset. These recommendations are additions to the ten original conservation recommendations provided as part of the 2014 consultation.

Conservation Recommendation 11: The Navy should work with NMFS and local agencies to develop a vessel grounding response plan that includes a funding mechanism and protocols for expedited vessel removal, damage assessment surveys, and strategies to offset any unavoidable loss to EFH resources (e.g., corals, seagrass, etc.). This would also inform and minimize potential cumulative adverse effects from unexpected groundings as MITT continues into the future.

Conservation Recommendation 12: Surveys should be performed annually at the Apra Harbor UNDET site to include georeferenced status and condition information for habitat forming EFH resources (e.g., corals and seagrass) within a 100-ft buffer surrounding the site. This will help to document potential adverse effects associated with both direct physical impacts and suspension of sediments to inform potential minimization (i.e., transplantation) and offset.

Conservation Recommendation 13: Shallow reef areas and reef flats that are being used for amphibious assaults should be surveyed immediately following each training exercise to document physical impacts, quantify coral condition, and stabilize and/or translocate any broken corals. NMFS is ready and willing to assist with such planning.

8

Conservation Recommendation 14: Implement a 300-yard buffer around coral reef habitats and as much as practicable avoid continuous emission of sounds (i.e., turn off vessel engines and sonar when not needed or in use) in these habitats. This would minimize potential adverse effects of chronic noise on corals (e.g., disruption of coral planulae settlement), Bottomfish MUS life history stages (e.g., hearing, immune system disruption, etc.), and reef fish (e.g., hearing, immune system disruption, etc.) that serve as prey-base for juvenile and adult Bottomfish MUS.

Conservation Recommendation 15: The Navy should ensure that in-water activities minimize potential introduction of nuisance or invasive species. Any vessels coming from outside of the CNMI's EEZ should comply with U.S. Coast Guard ballast water discharge standards (i.e. no ballast water discharge within 12 nautical miles or use approved ballast water management system) to prevent introduction of new invasive species. Any equipment, materials and gear entering the nearshore waters of Rota should also be checked prior to deployment.

Conservation Recommendation 16: The Navy should calculate MEM deposition and decomposition rates to determine maximum loads as this action becomes decadal. This would inform potential offset for potential cumulative adverse effects.

Conservation Recommendation 17: The Navy should conduct regular (i.e., every 3-5 years) quantitative resource survey assessments and updated benthic habitat substrate and biological cover mapping at representative nearshore sites to document cumulative impacts over time. This would reduce uncertainty, quantify changes in coral condition and state due to ongoing MITT activities, inform potential offset, and minimize cumulative adverse effects by informing adaptive management.

Conclusion

NMFS supports the need for military readiness and believes the mission of the Pacific Fleet is of utmost national security importance. NMFS supports Navy's intent to be good resource stewards and appreciate Navy's future effort in working with us to ensure that any unavoidable impacts to our trust resources are adequately mitigated. We therefore highlight the importance of continued cooperation and coordination to resolve NMFS's concerns. Also, NMFS is enclosing a report (Minton 2017) that provides a comprehensive review of typical adverse effects to EFH in the Pacific Islands region, which will be helpful to the Navy for future consultations. NMFS believes that our positive working relationship and mutual desire for a meaningful outcome for NOAA trust resources at risk while meeting the needs of the Fleet can be achieved. Please do not hesitate to contact Steve McKagan at 670-234-0004 and/or steven.mckagan@noaa.gov with any questions or to request further technical assistance.

C.4.3 NAVY RESPONSE LETTER TO NATIONAL MARINE FISHERIES SERVICE ESSENTIAL FISH HABITAT RECOMMENDATIONS

DEPARTMENT OF THE NAVY
COMMANDER
UNITED STATES PACIFIC FLEET
250 MAKALAPA DRIVE
PEARL HARBOR, HAWAII 96860-3131

IN REPLY REFER TO:
5090
Ser N465/0145
29 January 2020

Assistant Regional Administrator, Habitat Conservation Division
Pacific Islands Regional Office, National Marine Fisheries Service
1845 Wasp Boulevard, Building 176
Honolulu, HI 96818-5007

Dear Mr. Davis:

SUBJECT: NAVY FINAL RESPONSE TO THE NATIONAL MARINE FISHERIES SERVICE LETTER ON THE NAVY'S 2019 SUPPLEMENTAL ESSENTIAL FISH HABITAT ASSESSMENT IN SUPPORT OF THE MARIANA ISLANDS TRAINING AND TESTING SUPPLEMENTAL ENVIRONMENTAL IMPACT STATEMENT/OVERSEAS ENVIRONMENTAL IMPACT STATEMENT

The Navy thanks you for the comments provided in your letter of December 19, 2019, as well as the prompt review from your office of our supplemental Essential Fish Habitat Assessment for the Mariana Islands Training and Testing Supplemental Environmental Impact Statement/Overseas Environmental Impact Statement.

This letter contains enclosures that responds to the seven additional conservation recommendations to avoid, minimize, offset for, or otherwise mitigate potential impacts in your letter.

We thank you for your continued support of this critical project.

Sincerely,

D. A. McNAIR
Director, Environmental Readiness Division
By direction of the Commander

Enclosure: Navy Response To NMFS' December 19, 2019 Essential Fish Habitat Letter

Enclosure: Navy Response To NMFS' December 19, 2019 Essential Fish Habitat Letter

The U.S. Navy (Navy) addressed National Marine Fisheries Service Conservation Recommendations from the 2014 consultation in Table 4-2 of the Navy's 2019 supplemental Essential Fish Habitat Assessment (EFHA). This included incorporation of the Navy's original 2014 response to NMFS, as well as updated information addressing how some of the recommendations had been addressed.

The below text contains the Navy's response to the additional Conservation Recommendations from the NMFS letter to the Navy of December 19, 2019.

***NMFS Conservation Recommendation 11**: The Navy should work with NMFS and local agencies to develop a vessel grounding response plan that includes a funding mechanism and protocols for expedited vessel removal, damage assessment surveys, and strategies to offset any unavoidable loss to EFH resources (e.g., corals, seagrass, etc.). This would also inform and minimize potential cumulative adverse effects from unexpected groundings MITT continues into the future.*

Navy Response to Recommendation 11: Although a naval vessel grounded in 2017, the Navy asserts such events are not reasonably foreseeable impacts from the proposed action. Vessel groundings are rare and typically result from a series of unusual and unpredictable circumstances. The Navy is already prepared to respond to such events. The Navy maintains salvage and towing response capability through the employment of Navy assets and through worldwide salvage contracts. Contingency planning is required for preparedness, and the Navy can ensure that baseline conditions of natural resources within the management control of the Navy are identified and kept current through implementation of the 2019 Joint Region Marianas Integrated Natural Resources Management Plan to which NMFS is a signatory partner. Furthermore, the INRMP identifies strategies and actions to address Marine Habitat Management (Sections 5.4.2.1, 8.4.2.1, and 9.4.2.1) and Marine Protected Species Management (Section 5.4.2.3), specifically:

- "Develop protocol for immediate assessment and response to reef damage caused by unanticipated events such as ship groundings and anchor damage. The protocol will outline responsible parties, coordination process, and initial reef damage assessment requirements. This protocol will inform the long-term response plan."
- "Ensure no impact to coral or hard substrates during MITT training activities occurring within or adjacent to reef habitats by implementing appropriate avoidance measures."

Enclosure: Navy Response To NMFS' December 19, 2019 Essential Fish Habitat Letter

***NMFS Conservation Recommendation 12**: Surveys should be performed annually at the Apra Harbor UNDET site to include georeferenced status and condition information for habitat forming EFH resources (e.g., corals and seagrass) within a 100-ft buffer surrounding the site. This will help to document potential adverse effects associated with both direct physical impacts and suspension of sediments to inform potential minimization (i.e., transplantation) and offset.*

Navy Response to Recommendation 12: The Navy asserts this recommendation is already being satisfied under the mandates of the Joint Region Marianas INRMP, to which the NMFS is a signatory, as briefly summarized in the Navy's 2019 supplemental EFHA (page 5-2).. Details specific to previous surveys in Apra Harbor including the Outer Apra Harbor UNDET site can be found in the INRMP starting in Section 5.3. Continued similar efforts are recommended and planned in Sections 5.4.2 (Marine Ecosystems Management) as well as in Chapter 13 (Planning, Integration, and Implementation). Specific INRMP activities include:

- "Enhance coral habitat by monitoring health and acute impacts and through focused reef restoration efforts."
- "Establish long-term monitoring programs to track changes in the health of corals and water quality that are compatible with existing monitoring programs in Guam and the region. JRM has programmed for active/continuous remote monitoring of water quality parameters at select locations starting in FY19."
- "Work with regulatory partners and local subject matter experts to identify priority resilience indicators….The measures for assessing resilience include: macroalgae percent cover (to be obtained as coarse level data in the benthic habitat mapping project), coral community (available for some sites from past studies), bleaching resistance, coral recruitment and connectivity, coral diversity (available for some sites from past studies), herbivorous fish community (available for some of Apra Harbor from past studies), herbivore average functional group biomass, temperature variability, land-based sources of pollution, and accessibility due to wave exposure."
- "JRM will coordinate with local partners and subject matter experts (SMEs) to determine appropriate locations and methods for coral population enhancement and restoration efforts. JRM will align projects with the proposed Guam Restoration Strategy (in development). This may include projects that include sexual propagation that collect gametes, settle them on tiles, and eventually outplant new colonies, but can also include out-planting colonies, clones, or asexual propagation from fragments, or other restoration strategies such as algal removal."
- "Update and continuously maintain existing centralized GIS database to effectively inform and guide future management of marine natural resources on NBG Main Base and meet natural resources goals and objectives. Readily available GIS data will be used to develop natural resources constraints maps for use in current and future JRM management and planning decisions for NBG Main Base."

Enclosure: Navy Response To NMFS' December 19, 2019 Essential Fish Habitat Letter

***NMFS Conservation Recommendation 13**: Shallow reef areas and reef flats that are being used for amphibious assaults should be surveyed immediately following each training exercise to document physical impacts, quantify coral condition, and stabilize and/or translocate any broken corals. NMFS is ready and willing to assist with such planning.*

Navy Response to Recommendation 13: The Navy asserts this recommendation is already being satisfied under the mandates of the Joint Region Marianas INRMP, to which the NMFS is a signatory, as briefly summarized in the Navy's 2019 supplemental EFHA (page 5-2).. While not tied to specific training events, the INRMP directs repeated surveys across all submerged Navy controlled areas in the Mariana Islands. This would include beaches used for landing events. Cumulative impacts, if any can, be assessed over time as the program evolves. Additionally, the INRMP includes the previously described plans to develop protocols to respond to reef damage (Marine Habitat Management (Sections 5.4.2.1, 8.4.2.1, and 9.4.2 and Marine Protected Species Management Section 5.4.2.3). Specific INRMP activities include:

- "Enhance coral habitat by monitoring health and acute impacts and through focused reef restoration efforts."
- "Establish long-term monitoring programs to track changes in the health of corals and water quality that are compatible with existing monitoring programs in Guam and the region. JRM has programmed for active/continuous remote monitoring of water quality parameters at select locations starting in FY19."
- "Work with regulatory partners and local subject matter experts to identify priority resilience indicators….The measures for assessing resilience include: macroalgae percent cover (to be obtained as coarse level data in the benthic habitat mapping project), coral community (available for some sites from past studies), bleaching resistance, coral recruitment and connectivity, coral diversity (available for some sites from past studies), herbivorous fish community (available for some of Apra Harbor from past studies), herbivore average functional group biomass, temperature variability, land-based sources of pollution, and accessibility due to wave exposure."
- "JRM will coordinate with local partners and subject matter experts (SMEs) to determine appropriate locations and methods for coral population enhancement and restoration efforts. JRM will align projects with the proposed Guam Restoration Strategy (in development). This may include projects that include sexual propagation that collect gametes, settle them on tiles, and eventually outplant new colonies, but can also include out-planting colonies, clones, or asexual propagation from fragments, or other restoration strategies such as algal removal."
- "Develop protocol for immediate assessment and response to reef damage caused by unanticipated events such as ship groundings and anchor damage. The protocol will outline responsible parties, coordination process, and initial reef damage assessment requirements. This protocol will inform the long-term response plan."
- "Ensure no impact to coral or hard substrates during MITT training activities occurring within or adjacent to reef habitats by implementing appropriate avoidance measures."

While unrelated to specific training events, the 2019 JRM INRMP identifies the strategies and actions across all Navy submerged lands, to include coastal beaches, in the Mariana Islands. Cumulative impacts, if any, can, be assessed continually as the program evolves.

Enclosure: Navy Response To NMFS' December 19, 2019 Essential Fish Habitat Letter

***Conservation Recommendation 14**: Implement a 300-yard buffer around coral reef habitats and as much as practicable avoid continuous emission of sounds (i.e., turn off vessel engines and sonar when not needed or in use) in these habitats. This would minimize potential adverse effects of chronic noise on corals (e.g., disruption of coral planulae settlement), Bottomfish MUS life history stages (e.g., hearing, immune system disruption, etc.), and reef fish (e.g., hearing, immune system disruption, etc.) that serve as prey-base for juvenile and adult Bottomfish MUS.*

Navy Response to Recommendation 14: The Navy asserts meeting this recommendation is impractical and would jeopardize navigational safety, which could increase potential groundings. In practice, large naval vessels such as amphibious assault ships rarely close within 300 yards of a coastline. The NMFS recommendation would apply to landing craft, amphibious assault vehicles, and combat rubber raiding craft approaching or departing from a given landing location. However, these types of craft always need to maintain steerage way. In fact, the main objective is transporting personnel to and from a beach beyond a reef as quickly as possible; therefore, engines cannot be turned off. These types of craft would delay their approach, increasing the potential for drifting or potential grounding, which could present navigational hazards depending on the sea state (e.g., swamping). The Navy's 2019 Supplemental EFHA lists (in Table 4-2) ongoing standard operating procedures limiting the spatial spread of a landing (landing craft approaching in a line), as well as some engine noise (turning off combat rubber raiding craft motors to paddle across reefs to the beach). Finally, the Navy would not characterize the spatially and temporarily limited use of vessels during discreet training events as a chronic noise. There would be significant time between events (e.g., weeks or months) when landing events close to shore would not occur.

High-power sonar used for antisubmarine warfare would not generally occur within 3 NM of land, and hence would be well beyond the 300-yard buffer.

Enclosure: Navy Response To NMFS' December 19, 2019 Essential Fish Habitat Letter

***NMFS Conservation Recommendation 15**: The Navy should ensure that in-water activities minimize potential introduction of nuisance or invasive species. Any vessels coming from outside of the CNMI's EEZ should comply with U.S. Coast Guard ballast water discharge standards (i.e. no ballast water discharge within 12 nautical miles or use approved ballast water management system) to prevent introduction of new invasive species. Any equipment, materials and gear entering the nearshore waters of Rota should also be checked prior to deployment.*

Navy Response to Recommendation 15: The Navy asserts this recommendation is already being satisfied under the mandates of the Navy's internal compliance with established regulations. The Navy implements strict ballast water discharge requirements, consistent with the U.S. Environmental Protection Agency, U.S. Coast Guard, and adheres to applicable international regulations, through internal instructions, directions, and guidance. Vessels not equipped with ballast water treatment systems are required to perform exchanges greater than 12 NM from land or hold discharges, when appropriate and practicable, to minimize the introduction of invasive species.

The NMFS is a signatory to the 2019 JRM INRMP which identifies strategies and actions to address Marine Invasive Species Management (Sections 5.4.2.2, 8.4.2.2, 9.4.2.2, and 11.4.2.2), specifically:

- "Develop and maintain a Marine Invasive Species Management Plan for NBG Main Base, NCTS, AAFB, and Tinian MLA."
- "JRM will work with appropriate U.S. Navy commands to determine if updates are warranted for Navy hull husbandry standards (Naval Sea Systems Command S9086-CQ STM-010) (U.S. Navy 2006) and ballast water requirements (Note: The U.S. Navy adopts USCG standards)."
- "Participate in the quarterly Guam Invasive Species Advisory Council meetings and coordinate regularly with the territorial marine invasive species coordinator once hired."

Enclosure: Navy Response To NMFS' December 19, 2019 Essential Fish Habitat Letter

***NMFS Conservation Recommendation 16**: The Navy should calculate MEM deposition and decomposition rates to determine maximum loads as this action becomes decadal. This would inform potential offset for potential cumulative adverse effects.*

Navy Response to Recommendation 16: The Navy would reiterate that MEM use is across a very large spatial extent and rarely sequentially concentrated in small areas. Furthermore, the total cumulative MEM footprint as listed in Table 2-1 of the Navy's 2019 supplemental EFHA, is only 132,930 m^2 which is actually 37,866 m^2 less than the Navy's 2014 EFHA MEM footprint (170,796 m^2). Potential MEM footprint, 132,930 m^2 or 0.133 km^2, represents less than 0.0000001% of the total MITT study area (1,721,376 km^2).

Although absent in the MITT Draft Supplemental Environmental Impact Statement/Oversea Environmental Impact Statement (EIS/OEIS), the Navy has updated Appendix J (Statistical Probability Analysis for Estimating Direct Strike Impact and Number of Potential Exposures from Military Expended Materials) for the pending MITT final supplemental EIS/OEIS. This update will show the anticipated footprint of estimated annual MEM use, which can be summed across multiple years, or at least until a new supplemental EIS/OEIS is required. At that time, MEM usage would be re-evaluated. The Navy can provide the revised Appendix J to the NMFS as soon as final edits are complete. Finally, while the exact decomposition rates for all material in MEM is unknown, it is likely that major components such as aluminum and steel will corrode slowly in deep ocean waters. Overtime MEM would either be incorporated into sediments (i.e., buried) or remain on the ocean bottom subject to corrosion (Ocean News 2016, Edwards and Beldowski 2016[1]). Edwards and Beldowski 2016, alone with various contributing authors have documented the fate and condition of WWII munitions and post-war disposed items. Their work includes assessments corrosion of items deposited at a 300-600 m deep-water disposal site south of Oahu[2] (Figure 2).

Enclosure: Navy Response To NMFS' December 19, 2019 Essential Fish Habitat Letter

***NMFS Conservation Recommendation 17**: The Navy should conduct regular (i.e., every 3-5 years) quantitative resource survey assessments and updated benthic habitat substrate and biological cover mapping at representative nearshore sites to document cumulative impacts over time. This would reduce uncertainty, quantify changes in coral condition and state due to ongoing MITT activities, inform potential offset, and minimize cumulative adverse effects by informing adaptive management.*

Navy Response to Recommendation 17: The Navy asserts this recommendation has been identified in the 2019 JRM INRMP, as briefly summarized in the Navy's 2019 supplemental EFHA (page 5-2). The NMFS is a signatory to the 2019 JRM INRMP which identifies strategies and actions to address Marine Habitat Management (Sections 5.4.2.1, 8.4.2.1, 9.4.2.1, 11.4.2.1, and 12.4.2.1) and Marine Protected Species Management (Sections 5.4.2.3 and 11.4.2.3), specifically:

- "Enhance coral habitat by monitoring health and acute impacts and through focused reef restoration efforts."
- "Establish long-term monitoring programs to track changes in the health of corals and water quality that are compatible with existing monitoring programs in Guam and the region. JRM has programmed for active/continuous remote monitoring of water quality parameters at select locations starting in FY19."
- "Work with regulatory partners and local subject matter experts to identify priority resilience indicators….The measures for assessing resilience include: macroalgae percent cover (to be obtained as coarse level data in the benthic habitat mapping project), coral community (available for some sites from past studies), bleaching resistance, coral recruitment and connectivity, coral diversity (available for some sites from past studies), herbivorous fish community (available for some of Apra Harbor from past studies), herbivore average functional group biomass, temperature variability, land-based sources of pollution, and accessibility due to wave exposure."
- "JRM will coordinate with local partners and subject matter experts (SMEs) to determine appropriate locations and methods for coral population enhancement and restoration efforts. JRM will align projects with the proposed Guam Restoration Strategy (in development). This may include projects that include sexual propagation that collect gametes, settle them on tiles, and eventually outplant new colonies, but can also include out-planting colonies, clones, or asexual propagation from fragments, or other restoration strategies such as algal removal."
- "Develop protocol for immediate assessment and response to reef damage caused by unanticipated events such as ship groundings and anchor damage. The protocol will outline responsible parties, coordination process, and initial reef damage assessment requirements. This protocol will inform the long-term response plan."
- "Ensure no impact to coral or hard substrates during MITT training activities occurring within or adjacent to reef habitats by implementing appropriate avoidance measures."

Enclosure: Navy Response To NMFS' December 19, 2019 Essential Fish Habitat Letter

Additionally, the 2019 JRM INRMP identifies planning, integration, and implementation strategies to coordinate natural resources requirements with other federal, territorial, or commonwealth agencies, including the acquisition of INRMP mutual agreements between the DON, USFWS, NOAA-NMFS, and territorial and commonwealth fish and wildlife agencies (see Chapter 13).

C.4.4 National Marine Fisheries Service Response Letter to the Navy

U.S. DEPARTMENT OF COMMERCE
National Oceanic and Atmospheric Administration
NATIONAL MARINE FISHERIES SERVICE
Pacific Islands Regional Office

Honolulu, Hawaii 96818
(808) 725-5000 · Fax: (808) 725-5215

Mr. D. A. McNair
Director, Environmental Readiness
Department of Navy
United States Pacific Fleet
250 Makalapa Drive
Pearl Harbor, HI 96860-3131

February 7, 2020

Dear Mr. McNair:

On January 29, 2020, the National Marine Fisheries Service, Pacific Islands Regional Office, Habitat Conservation Division (NMFS) received your letter by direction of the Commander, U.S. Pacific Fleet (hereafter, Navy) titled 'Navy Final Response To The National Marine Fisheries Service Letter On Navy's 2019 Supplemental Essential Fish Habitat Assessment In Support Of The Mariana Islands Training And Testing Supplemental Environmental Impact Statement/Overseas Environmental Impact Statement'. The Navy's letter provides individual responses to each of the Essential Fish Habitat (EFH) conservation recommendations that we provided in response to the supplemental Mariana Islands Training and Testing (MITT) EHF consultation.

NMFS would like to thank the Navy for taking a close look at each of the new conservation recommendations that we put forward as part of this Supplemental Environmental Impact Statement (SEIS) for MITT activities. Furthermore, NMFS is proud of the progress we have made as a partner and signatory on the Joint Region Marianas (JRM) Integrated Natural Resource Management Plan (INRMP), which was completed in June 2019. The INRMP, as referenced in your letter, is full of progressive strategies and actions which have the potential to address many of our conservation concerns if implemented in an effective and coordinated fashion. NMFS agrees with Navy that the JRM INRMP will be an important tool in the avoidance, minimization, and offset of adverse effects to EFH resulting from MITT activities. However, we are not comfortable deferring each of the proposed conservation recommendations to the INRMP. We request to continue our ongoing coordination to better understand a) the current status of INRMP projects directly related to our MITT-specific EFH concerns, and b) future planning and funding of INRMP projects to better understand how and when the products of these projects could be applied to our MITT-specific EFH concerns.

Doc. No. 35GL-20-1874.*

NMFS Responses

Navy has opted not to accept any of the seven new conservation recommendations provided as part of the supplemental EFH consultation and has instead asserted that NMFS concerns are already addressed through existing procedures (CR#'s 11, 15), are covered by the INRMP (CR#'s 11, 12, 13, 15, 17), are impractical (CR#14), or are minimal at large spatial scales (CR#16). Below, we restate all conservation recommendations, Navy responses; and the subsequent responses by NMFS either accepting the responses by Navy, maintaining our position, or providing opportunities for ongoing partnership to meet our shared conservation goals.

Below, and pursuant to the EFH provisions of the Magnuson-Stevens Fishery Conservation and Management Act (Magnuson-Stevens Act, Section 305(b) as described by 50 CFR 600.920), NMFS evaluates the sufficiency of Navy responses.

Conservation Recommendation 11 (CR#11): Navy should work with NMFS and local agencies to develop a vessel grounding response plan that includes a funding mechanism and protocols for expedited vessel removal, damage assessment surveys, and strategies to offset any unavoidable loss to EFH resources (e.g., corals, seagrass, etc.). This would also inform and minimize potential cumulative adverse effects from unexpected groundings MITT continues into the future.

Navy Response: Although a naval vessel grounded in 2017, Navy asserts such events are not reasonably foreseeable impacts from the proposed action. Vessel groundings are rare and typically result from a series of unusual and unpredictable circumstances. Navy is already prepared to respond to such events. Navy maintains salvage and towing response capability through the employment of Navy assets and through worldwide salvage contracts. Contingency planning is required for preparedness, and Navy can ensure that baseline conditions of natural resources within the management control of Navy are identified and kept current through implementation of the 2019 Joint Region Marianas Integrated Natural Resources Management Plan to which NMFS is a signatory partner. Furthermore, the INRMP identifies strategies and actions to address Marine Habitat Management (Sections 5.4.2.1, 8.4.2.1, and 9.4.2.1) and Marine Protected Species Management (Section 5.4.2.3), specifically:

- "Develop protocol for immediate assessment and response to reef damage caused by unanticipated events such as ship groundings and anchor damage. The protocol will outline responsible parties, coordination process, and initial reef damage assessment requirements. This protocol will inform the long-term response plan."
- "Ensure no impact to coral or hard substrates during MITT training activities occurring within or adjacent to reef habitats by implementing appropriate avoidance measures."

NMFS Response: We appreciate Navy's readiness to respond to grounding events and intent to better integrate damage assessment and mitigation protocols through the INRMP. We agree that the INRMP provides an opportunity to address this conservation recommendation, but would like to further coordinate with the Navy to ensure that our MITT-specific EFH concerns are proactively integrated into the projects currently being developed within the INRMP while working collectively to help enable funding of these projects and their deliverables. NMFS would like to suggest that we schedule a meeting with the MITT Environmental Readiness Division, INRMP project leads and other stakeholders to discuss how to ensure the strategies and activities stemming

Doc. No. 35GL-20-1874.*

from the new INRMP translate to projects and outcomes that satisfy this conservation recommendation.

Conservation Recommendation 12 (CR#12): Surveys should be performed annually at the Apra Harbor UNDET site to include georeferenced status and condition information for habitat forming EFH resources (e.g., corals and seagrass) within a 100-ft buffer surrounding the site. This will help to document potential adverse effects associated with both direct physical impacts and suspension of sediments to inform potential minimization (i.e., transplantation) and offset.

Navy Response: The Navy asserts this recommendation is already being satisfied under the mandates of the Joint Region Marianas INRMP, to which the NMFS is a signatory, as briefly summarized in the Navy's 2019 supplemental EFHA (page 5-2).. Details specific to previous surveys in Apra Harbor including the Outer Apra Harbor UNDET site can be found in the INRMP starting in Section 5.3. Continued similar efforts are recommended and planned in Sections 5.4.2 (Marine Ecosystems Management) as well as in Chapter 13 (Planning, Integration, and Implementation). Specific INRMP activities include:

- "Enhance coral habitat by monitoring health and acute impacts and through focused reef restoration efforts."
- "Establish long-term monitoring programs to track changes in the health of corals and water quality that are compatible with existing monitoring programs in Guam and the region. JRM has programmed for active/continuous remote monitoring of water quality parameters at select locations starting in FY19."
- "Work with regulatory partners and local subject matter experts to identify priority resilience indicators….The measures for assessing resilience include: macroalgae percent cover (to be obtained as coarse level data in the benthic habitat mapping project), coral community (available for some sites from past studies), bleaching resistance, coral recruitment and connectivity, coral diversity (available for some sites from past studies), herbivorous fish community (available for some of Apra Harbor from past studies), herbivore average functional group biomass, temperature variability, land-based sources of pollution, and accessibility due to wave exposure."
- "JRM will coordinate with local partners and subject matter experts (SMEs) to determine appropriate locations and methods for coral population enhancement and restoration efforts. JRM will align projects with the proposed Guam Restoration Strategy (in development). This may include projects that include sexual propagation that collect gametes, settle them on tiles, and eventually outplant new colonies, but can also include out-planting colonies, clones, or asexual propagation from fragments, or other restoration strategies such as algal removal."
- "Update and continuously maintain existing centralized GIS database to effectively inform and guide future management of marine natural resources on NBG Main Base and meet natural resources goals and objectives. Readily available GIS data will be used to develop natural resources constraints maps for use in current and future JRM management and planning decisions for NBG Main Base."

NMFS Response: We agree that the INRMP provides an opportunity to address this conservation recommendation, but would like to further coordinate with the Navy to ensure that our MITT-

specific EFH concerns are proactively integrated into the projects currently being developed within the INRMP while working collectively to help enable funding of these projects and their deliverables. NMFS would like to suggest that we schedule a meeting with the MITT Environmental Readiness Division, INRMP project leads and other stakeholders to discuss how to ensure the strategies and activities stemming from the new INRMP translate to projects and outcomes that satisfy this conservation recommendation.

Conservation Recommendation 13 (CR#13): Shallow reef areas and reef flats that are being used for amphibious assaults should be surveyed immediately following each training exercise to document physical impacts, quantify coral condition, and stabilize and/or translocate any broken corals. NMFS is ready and willing to assist with such planning.

Navy Response: The Navy asserts this recommendation is already being satisfied under the mandates of the Joint Region Marianas INRMP, to which the NMFS is a signatory, as briefly summarized in the Navy's 2019 supplemental EFHA (page 5-2).. While not tied to specific training events, the INRMP directs repeated surveys across all submerged Navy controlled areas in the Mariana Islands. This would include beaches used for landing events. Cumulative impacts, if any can, be assessed over time as the program evolves. Additionally, the INRMP includes the previously described plans to develop protocols to respond to reef damage (Marine Habitat Management (Sections 5.4.2.1, 8.4.2.1, and 9.4.2 and Marine Protected Species Management Section 5.4.2.3). Specific INRMP activities include:

- "Enhance coral habitat by monitoring health and acute impacts and through focused reef restoration efforts."
- "Establish long-term monitoring programs to track changes in the health of corals and water quality that are compatible with existing monitoring programs in Guam and the region.
- JRM has programmed for active/continuous remote monitoring of water quality parameters at select locations starting in FY19."
- "Work with regulatory partners and local subject matter experts to identify priority resilience indicators….The measures for assessing resilience include: macroalgae percent cover (to be obtained as coarse level data in the benthic habitat mapping project), coral community (available for some sites from past studies), bleaching resistance, coral recruitment and connectivity, coral diversity (available for some sites from past studies), herbivorous fish community (available for some of Apra Harbor from past studies), herbivore average functional group biomass, temperature variability, land-based sources of pollution, and accessibility due to wave exposure."
- "JRM will coordinate with local partners and subject matter experts (SMEs) to determine appropriate locations and methods for coral population enhancement and restoration efforts. JRM will align projects with the proposed Guam Restoration Strategy (in development). This may include projects that include sexual propagation that collect gametes, settle them on tiles, and eventually outplant new colonies, but can also include out-planting colonies, clones, or asexual propagation from fragments, or other restoration strategies such as algal removal."
- "Develop protocol for immediate assessment and response to reef damage caused by unanticipated events such as ship groundings and anchor damage. The protocol will

outline responsible parties, coordination process, and initial reef damage assessment requirements.

- This protocol will inform the long-term response plan."
- "Ensure no impact to coral or hard substrates during MITT training activities occurring within or adjacent to reef habitats by implementing appropriate avoidance measures."

While unrelated to specific training events, the 2019 JRM INRMP identifies the strategies and actions across all Navy submerged lands, to include coastal beaches, in the Mariana Islands. Cumulative impacts, if any, can, be assessed continually as the program evolves.

NMFS Response: We agree that the INRMP provides an opportunity to address this conservation recommendation, but would like to further coordinate with the Navy to ensure that our MITT-specific EFH concerns are proactively integrated into the projects currently being developed within the INRMP while working collectively to help enable funding of these projects and their deliverables. NMFS would like to suggest that we schedule a meeting with the MITT Environmental Readiness Division, INRMP project leads and other stakeholders to discuss how to ensure the strategies and activities stemming from the new INRMP translate to projects and outcomes that satisfy this conservation recommendation.
